A. REPRESENTATION THEORY FOR SPACE GROUPS

Three types of irreducible representations

An irreducible representation (irrep) $D(g)$ of a group G must fall under one of the following categories: real irreps, complex irreps, and pseudo-real irreps. $D(g)$ is a real irrep, if $D(g)$ is equivalent to its complex conjugate, given by

$$D(g)^* = \mathcal{V} D(g) \mathcal{V}^\dagger \,, \tag{S1}$$

and the unitary matrix $\mathcal{V}$ satisfies $\mathcal{V} = \mathcal{V}^T$. If $\mathcal{V}$ is a symmetric matrix, $(\mathcal{V}^{-1/2})$ is also a symmetric matrix. By performing a unitary transformation with $(\mathcal{V}^{-1/2})^*$, we find that $D'(g) = (\mathcal{V}^{-1/2})^* D(g) (\mathcal{V}^{-1/2})^T$ satisfy that

$$\begin{aligned} D'(g)^* &= \mathcal{V}^{-1/2} D(g)^* (\mathcal{V}^{-1/2})^\dagger \\ &= (\mathcal{V}^{-1/2}) \mathcal{V} D(g) \mathcal{V}^\dagger (\mathcal{V}^{-1/2})^\dagger \\ &= (\mathcal{V}^{-1/2}) \mathcal{V} (\mathcal{V}^{-1/2})^T D'(g) (\mathcal{V}^{-1/2})^* \mathcal{V}^\dagger (\mathcal{V}^{-1/2})^\dagger \\ &= D'(g) \quad \forall g \in G \end{aligned} \tag{S2}$$

This implies that all elements of the real irrep can be made real by properly choosing a basis. $D(g)$ is a pesudo-real irrep, if $D(g)^* = \mathcal{V} D(g) \mathcal{V}^\dagger$, and $\mathcal{V}$ satisfies $\mathcal{V} = -\mathcal{V}^T$. As $\mathcal{V}$ is an anti-symmetric matrix, its dimension must be even, and consequently, the dimension of $D(g)$ must be even. (Suppose the dimension of $\mathcal{V}$ is odd, then $\mathcal{V} = -\mathcal{V}^T$ leads to $\det V = -\det V$ and hence $\det \mathcal{V} = 0$, contradicts with the unitary condition of $\mathcal{V}$.) Note that $\mathcal{V}^{1/2}$ is neither symmetric nor anti-symmetric. If $\mathcal{V}^{1/2}$ was symmetric or anti-symmetric, $\mathcal{V} = \mathcal{V}^{1/2} \mathcal{V}^{1/2}$ should be symmetric, which leads to a contradiction. Thus, we cannot choose a basis in which all elements of $D(g)$ are real as in Eq. (S2), even though $D(g)$ is equivalent to its complex conjugate. If $D(g)$ is not equivalent to its complex conjugate, it is a complex irrep. Under any basis, some elements of $D(g)$ must be complex.

A direct sum of an irrep and its complex conjugate can be made real. Let $D_{ir}(g)$ be a complex or pseudo-real irrep, and let $D_r(g)$ be the direct sum of $D_{ir}(g)$ and its complex conjugate:

$$D_r(g) = \begin{pmatrix} D_{ir}(g) & 0 \\ 0 & D_{ir}(g)^* \end{pmatrix} . \tag{S3}$$

Note that if $D_{ir}(g)$ is pseudo-real, $D_r(g)$ is a direct sum of two equivalent pseudo-real irreps. The matrix $D_r(g)$ satisfies that

$$D_r(g)^* = \sigma_x D_r(g) \sigma_x \, \forall g \in G \,, \tag{S4}$$

and σ_x is a symmetric matrix. Thus, with unitary transformation $\sigma_x^{1/2}$, we can make $D_r(g)$ a real matrix as in Eq. (S2).

We have shown that the representation matrices of a single complex irrep or a single pseudo-real irrep are necessarily complex in any basis, while the representation matrices of a conjugate pair of complex irreps or a pair of equivalent pseudo-real irreps can be made real. In summary, a real representation must be decomposed into real irreps, conjugate pairs of complex irreps, or pairs of equivalent pseudo-real irreps.

Irreducible representations of the little groups of space groups

To study the irreps of a space group P, we first consider its translation subgroup T, given as

$$T = \left\{ \{1|\boldsymbol{v}\} \middle| \{1|\boldsymbol{v}\} \in P \right\} , \tag{S5}$$

and irreps of T. Since T is an Abliean group, it can only possess 1D irreps. An irrep $\boldsymbol{\Gamma}^k$ of T is characterized by a vector $\boldsymbol{k}$ in the BZ, and the representation matrix $D_{\boldsymbol{\Gamma}^k}(\{1|\boldsymbol{v}\}) = e^{i\boldsymbol{k}\cdot\boldsymbol{v}}$. Since $\boldsymbol{k}\cdot\boldsymbol{v}$ is a phase factor, two vectors $\boldsymbol{k}_1$ and $\boldsymbol{k}_2$ in the BZ are considered equivalent ($\boldsymbol{k}_1 \equiv \boldsymbol{k}_2$) if they satisfy the relation

$$\boldsymbol{k}_1 = \boldsymbol{k}_2 + \sum_{i=1}^{3} m_i \boldsymbol{b}_i, \quad m_i \in \mathbb{Z}, \tag{S6}$$

where $\boldsymbol{b}_i$ represents reciprocal lattice vectors, and $\boldsymbol{b}_i$ and the primitive lattice vectors $\boldsymbol{a}_i$ of T satisfy $\boldsymbol{a}_i \cdot \boldsymbol{b}_j = 2\pi\delta_{i,j}$ for $i, j = 1, 2, 3$.

Next, let us consider the little group $P^{\boldsymbol{k}}$ of $\boldsymbol{k}$ and its allowable irreps $\rho^{\boldsymbol{k}}$. The little group $P^{\boldsymbol{k}}$ of $\boldsymbol{k}$ is defined as

$$P^{\boldsymbol{k}} = \left\{ \{R|\boldsymbol{v}\} \middle| \{R|\boldsymbol{v}\} \in P,\ R\boldsymbol{k} \equiv \boldsymbol{k} \right\} . \tag{S7}$$

Based on this definition, the translation group T is a subgroup of $P^{\boldsymbol{k}}$, and we can decompose $P^{\boldsymbol{k}}$ into cosets with respect to T

$$P^{\boldsymbol{k}} = \{R_1|\boldsymbol{v}_1\}T + \{R_2|\boldsymbol{v}_2\}T + \cdots + \{R_m|\boldsymbol{v}_m\}T \,. \tag{S8}$$

The point-group parts $R_1, R_2, \cdots, R_m$ must be distinct from one another and form a point group, which is referred to as

* These authors contribute equally to this work.
† songzd@pku.edu.cn

the little co-group $\bar{P}^{\boldsymbol{k}}$. An allowable irrep $\rho_{\boldsymbol{k}}$ of $P^{\boldsymbol{k}}$ satisfies $D_{\rho_{\boldsymbol{k}}}(\{1|\boldsymbol{v}\}) = e^{i\boldsymbol{k}\cdot\boldsymbol{v}}1_{r\times r}$, where r is the dimension of $\rho_{\boldsymbol{k}}$. All the allowable irreps of $P^{\boldsymbol{k}}$ can be obtained from (projective) irreps of the little co-group $\bar{P}^{\boldsymbol{k}}$. To see this, let us consider the representation matrices of the coset representatives $\{R_i|\boldsymbol{v}_i\}$ $(i = 1, 2, \cdots, m)$ and their multiplication

$$D_{\rho_{\boldsymbol{k}}}(\{R_i|\boldsymbol{v}_i\})D_{\rho_{\boldsymbol{k}}}(\{R_j|\boldsymbol{v}_j\}) = D_{\rho_{\boldsymbol{k}}}(\{R_iR_j|R_i\boldsymbol{v}_j + \boldsymbol{v}_i\}). \tag{S9}$$

Suppose R_iR_j is identical to $R_{f(i,j)}$, where $f(i,j) \in \{1, 2, \cdots, m\}$. Then, we have

$$\begin{aligned} &D_{\rho_{\boldsymbol{k}}}(\{R_i|\boldsymbol{v}_i\})D_{\rho_{\boldsymbol{k}}}(\{R_j|\boldsymbol{v}_j\}) \\ =&D_{\rho_{\boldsymbol{k}}}(\{1|R_i\boldsymbol{v}_j + \boldsymbol{v}_i - \boldsymbol{v}_{f(i,j)}\})D_{\rho_{\boldsymbol{k}}}(\{R_{f(i,j)}|\boldsymbol{v}_{f(i,j)}\}) \\ =&e^{i\boldsymbol{k}\cdot\left(R_i\boldsymbol{v}_j+\boldsymbol{v}_i-\boldsymbol{v}_{f(i,j)}\right)}D_{\rho_{\boldsymbol{k}}}(\{R_{f(i,j)}|\boldsymbol{v}_{f(i,j)}\}). \end{aligned} \tag{S10}$$

Thus, the allowable irrep $D_{\rho_{\boldsymbol{k}}}(\{R_i|v_i\})$ can also be understood as a projective irrep of the point-group operation $R_i \in \bar{P}^{\boldsymbol{k}}$ with a factor system given by $e^{i\boldsymbol{k}\cdot\left(R_i\boldsymbol{v}_j+\boldsymbol{v}_i-\boldsymbol{v}_{f(i,j)}\right)}$. In the other way, all allowable irreps of the little group $P^{\boldsymbol{k}}$ can be obtained from the irrep of the little co-group $\bar{P}^{\boldsymbol{k}}$ with the projective phase given by Eq. (S10).

B. EQUIVALENCE BETWEEN O(N) REPRESENTATIONS

In this section, we present some technique details for utilizing equivalence relationship between O(N) representations.

Choices of unit cells in different space groups

We begin by discussing the restrictions imposed by the Bravais lattice setting on the lattice vector transformation matrix V. Subsequently, we present an algorithm for enumerating all possible choices of the unit cell for different space groups.

Suppose the lattice basis for a space group is $\boldsymbol{a}_i$ $(i = 1, 2, 3)$, and a transformation matrix V satisfies that $V\boldsymbol{a}_i = \sum_{j=1}^{3}\boldsymbol{a}_jM_{ji}$. Then, on the basis $\boldsymbol{a}_i$'s, the matrix V should be represented as M. As discussed in Sec. II D in the main text, for any space group, M must satisfy that $\det M = 1$ and $M_{ij} \in \mathbb{Z}$. The Bravais lattice should remain unchanged under the action of M. It implies that the transformed unit cell satisfies the same restrictions regarding the interaxial angles α, β, γ, the relative relationship of the lengths a, b, c of the lattice vectors, and the choice of rotation axes as the original unit cell. The requirements for each lattice system are summarized below:

- Triclinic lattice: The only requirements for M are that $\det M = 1$ and $M_{ij} \in \mathbb{Z}$, as the interaxial angles α, β, γ and lattice lengths a, b, c are all distinct.

- Monoclinic lattice: In this case, $\boldsymbol{a}_2$ represents the unique 2-fold rotation axis, and $\alpha = \gamma = \pi/2$. As a result, M can be block diagonalized into a transformation $M_{xz} = \begin{pmatrix} M_{11} & M_{13} \\ M_{31} & M_{33} \end{pmatrix}$ within the $\boldsymbol{a}_1, \boldsymbol{a}_3$ plane and a transformation along $\boldsymbol{a}_2$. $V\boldsymbol{a}_2 = M_{22}\boldsymbol{a}_2$ can be either $\boldsymbol{a}_2$ or $-\boldsymbol{a}_2$. As β does not necessarily equal $\pi/2$ and a does not necessarily equal b, they do not impose any restrictions on M_{xz}. As $\det M = 1$, if $M_{22} = 1$ (-1), M_{xz} is an integer matrix with determinant 1 (-1).

- Orthorhombic lattice: $\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3$ are all two-fold rotation axes. Consequently, $V\boldsymbol{a}_i$ $(i = 1, 2, 3)$ can be any of $\pm\boldsymbol{a}_1, \pm\boldsymbol{a}_2, \pm\boldsymbol{a}_3$. The condition $\alpha = \beta = \gamma = \pi/2$ requires that M be an orthogonal matrix. Thus, M must be a rotation in the octahedral point group O.

- Tetragonal lattice: The condition $\alpha = \beta = \gamma = \pi/2$ necessitates M being an orthogonal matrix. Furthermore, $M\boldsymbol{a}_3$ should be parallel to $\boldsymbol{a}_3$, which is the unique 4-fold rotation axis. $V\boldsymbol{a}_1$ can only be one of $\pm\boldsymbol{a}_1, \pm\boldsymbol{a}_2$. Therefore, V (and M) must be a rotation in the dihedral group D_4.

- Hexagonal lattice: $\boldsymbol{a}_3$ represents the unique 6-fold or 3-fold rotation axis, and $\alpha = \gamma = \pi/2$. Consequently, $V\boldsymbol{a}_3$ should be parallel to $\boldsymbol{a}_3$, and $V\boldsymbol{a}_1$ and $V\boldsymbol{a}_2$ should remain within the same plane as $\boldsymbol{a}_1$ and $\boldsymbol{a}_2$. Additionally, $V\boldsymbol{a}_{1,2}$ still represents a lattice translation and can only be one of $\pm\boldsymbol{a}_1$, $\pm\boldsymbol{a}_2$, and $\pm(\boldsymbol{a}_1 + \boldsymbol{a}_2)$. Therefore, V must correspond to an operation in the D_6 group.

- Rhombohedral lattice: $a = b = c$, $\alpha = \beta = \gamma$, $\boldsymbol{a}_1 + \boldsymbol{a}_2 + \boldsymbol{a}_3$ is the unique rotation axis. $V\boldsymbol{a}_i$ $(i = 1, 2, 3)$ can only be one of $\pm\boldsymbol{a}_1, \pm\boldsymbol{a}_2, \pm\boldsymbol{a}_3$. Once $V\boldsymbol{a}_1$ is specified, $V\boldsymbol{a}_2$ and $V\boldsymbol{a}_3$ are also uniquely determined. Such V's form the dihedral group D_3.

- For cubic lattice, $\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3$ are all four-fold rotation axes. Consequently, $V\boldsymbol{a}_i$ $(i = 1, 2, 3)$ can be any of $\pm\boldsymbol{a}_1, \pm\boldsymbol{a}_2, \pm\boldsymbol{a}_3$. The condition $\alpha = \beta = \gamma = \pi/2$ requires V to be an orthogonal matrix. Thus, V (and M) must be a rotation in the octahedral point group O.

In the following, we will introduce the algorithm for enumerating all possible choices of the unit cell for a given space group. We note that according to Eq. (17) in the main text, the product of two allowable coordinate transformations is still allowable. Thus, all allowable coordinate transformations $\{V|\boldsymbol{t}\}$ form a group P_C, which generally has infinite order, and we only need to enumerate their generators.

P_C can be decomposed as $P_C = T_C \rtimes V_C$, where T_C contains all allowable origin shift $\boldsymbol{t}$, and V_C contains rotations of the lattice axes. We only need to enumerate elements in T_C and the coset representatives of P_C/T_C.

Let us first consider T_C. If $\boldsymbol{t}$ is a lattice vector, it must produce an automorphism [Eq. (17) in the main text], but it will not transform an irrep into a different one. Consider an irrep $\rho_{\boldsymbol{k}} \uparrow P$ of space group P, which is induced by an irrep $\rho_{\boldsymbol{k}}$ of the little group $P^{\boldsymbol{k}}$ of vector $\boldsymbol{k}$. We investigate how irrep $\rho_{\boldsymbol{k}}$ of the little group is transformed under an origin shift $\boldsymbol{t}$, where $\boldsymbol{t}$ is a lattice vector. Note that $\{1|\boldsymbol{t}\} \in \rho_{\boldsymbol{k}}$ and $\rho_{\boldsymbol{k}}(\{1|\boldsymbol{t}\}) = e^{i\boldsymbol{k}\cdot t}1_{m_{\boldsymbol{k}}\times m_{\boldsymbol{k}}}$, where $m_{\boldsymbol{k}}$ is the dimension of $\rho_{\boldsymbol{k}}$. According to Eq. (18) in the main text, the transformed irrep

$\rho'_{\boldsymbol{k}}(g)$ ($g \in P^{\boldsymbol{k}}$) is given as

$$\begin{aligned}\rho'_{\boldsymbol{k}}(g) &= \rho_{\boldsymbol{k}}(\{1|\boldsymbol{t}\}g\{1|\boldsymbol{t}\}^{-1}) \\ &= \rho_{\boldsymbol{k}}(\{1|\boldsymbol{t}\})\rho_{\boldsymbol{k}}(g)\rho_{\boldsymbol{k}}(\{1|\boldsymbol{t}\}^{-1}) \\ &= e^{i\boldsymbol{k}\cdot t}1_{m_{\boldsymbol{k}}\times m_{\boldsymbol{k}}}\rho_{\boldsymbol{k}}(g)e^{-i\boldsymbol{k}\cdot t}1_{m_{\boldsymbol{k}}\times m_{\boldsymbol{k}}} \\ &= \rho_{\boldsymbol{k}}(g)\,.\end{aligned} \tag{S11}$$

$\rho'_{\boldsymbol{k}}$ is the same little group irrep as $\rho^{\boldsymbol{k}}$, and therefore, they induce the same irrep of the space group P. Thus, we only need to consider $\boldsymbol{t}$ within the primitive unit cell. According to Eq. (17) in the main text, allowable $\boldsymbol{t}$ satisfies the condition:

$$R_p\boldsymbol{t} - \boldsymbol{t} = \sum_{i=1}^{3} m_i\boldsymbol{a}_i\,(m_i \in \mathbb{Z})\,, \forall p \in P\,, \tag{S12}$$

where R_p is the point-group part of operation g. It implies that the new origin must have all point-group symmetries of this space group, and $\boldsymbol{t}$ is solely determined by R_g. In some groups, $\boldsymbol{t}$ can only take discrete groups, such as groups with inversion symmetry. Eq. (S12) implies that the shifted origin should be an inversion-invariant point. In other groups, $\boldsymbol{t}$ can take continuous values. For example, in group P1 (No. 1), $\boldsymbol{t}$ can be an arbitrary vector in the whole space since R_p is always 1. In such cases, we consider a subgroup T_{C0} of T_C, in which $R_p\boldsymbol{t} - \boldsymbol{t} = 0, \forall p \in P$. T_{C0} contains allowable origin shift that can be continuously connected into an identity operation. If $\{1|\boldsymbol{t}\} \in T_{C0}$, $\{1|\boldsymbol{t}\}^{-1}\{R|\boldsymbol{v}\}\{1|\boldsymbol{t}\} = \{R|\boldsymbol{v} + (R-1)\boldsymbol{t}\} = \{R|\boldsymbol{v}\}$. An origin shift in T_{C0} will not transform a space-group operation or an irrep into a different one. Therefore, we only need to consider the effect of coset representatives of T_C/T_{C0} on the irreps. T_C/T_{C0} only takes discrete values and only contains a finite number of $\boldsymbol{t}$ in the primitive unit cell. Thus, for each group, we can obtain a finite number of allowable $\boldsymbol{t}$, and these $\{1|\boldsymbol{t}\}$ serve as one part of generators of the allowable coordinate transformation.

To study V_C, we proceed as follows. In five lattice systems except for triclinic and monoclinic lattice, the number of choices of V is finite due to the restrictions imposed by Bravais lattices, as discussed earlier in this section. For each space group P in these lattice systems and for each V, we perform a numerical search for a $\boldsymbol{t}$ within the unit cell that satisfies Eq. (17) in the main text. If such a $\boldsymbol{t}_V$ exists, we include $\{V|\boldsymbol{t}_V\}$ into the coset representatives of P_C/T_C. For space groups ($P1$ and $P\bar{1}$) in triclinic lattices, all matrices $M \in SL_3(\mathbb{Z})$ are compatible with Bravais lattices (M is the representation matrix of V on the lattice basis). Using Eq. (17) in the main text, one can check that in space groups $P1$ and $P\bar{1}$, for arbitrary $M \in SL_3(\mathbb{Z})$ $\{M|\boldsymbol{0}\}$ is an allowable coordinate transformation, implying that the all the coset representatives of P_C/T_C can always be chosen to have the form $\{M|\boldsymbol{0}\}$. Thus, we can choose generators (for example, see Ref. [1]) of the group $SL_3(\mathbb{Z})$ as coset representatives P_C/T_C.

We need to apply a more careful treatment for space groups in the monoclinic lattice systems. As discussed earlier, due to the restriction on Bravais lattice, M belongs to one of these two sets

$$S_I = \left\{ \begin{pmatrix} M_{11} & 0 & M_{13} \\ 0 & 1 & 0 \\ M_{31} & 0 & M_{33} \end{pmatrix} \middle| M_{xz} = \begin{pmatrix} M_{11} & M_{13} \\ M_{31} & M_{33} \end{pmatrix} \in SL_2(\mathbb{Z}) \right\} \tag{S13}$$

or

$$M_{\boldsymbol{x}}(\pi)S_I \quad \text{with} \quad M_{\boldsymbol{x}}(\pi) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \tag{S14}$$

The generators of $SL_2(\mathbb{Z})$ are given as

$$\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{S15}$$

We note that $\{M_{\boldsymbol{x}}(\pi)|\boldsymbol{0}\}$ that reverses the y, z directions is an allowable coordinate transformation for all space groups with Monoclinic lattice, and hence it serves as a coset representative of P_C/T_C. While the number of transformation matrices in S_I is infinite, we can generate them successively by the generators [Eq. (S15)]. For each generated M_I and the corresponding V_I, we perform a numerical search within the unit cell to find a $\boldsymbol{t}_V$ that satisfies Eq. (17) in the main text. We add $\{V_I|\boldsymbol{t}_{V_I}\}$ to the coset representatives of P_C/T_C if such a $\boldsymbol{t}_{V_I}$ exists. This process continues until the newly generated V_I, which is determined as allowable, can be generated by those already in the set of coset representatives.

In summary, the methods described above allow us to obtain the generators of allowable coordinate transformations for every space group. These generators consist of generators for origin shifts and generators for changing the axes of the unit cell.

Example: type-V O(3) representations of space group $P3$

As established in Sec. II D in the main text, O(3) representations of different types do not deform into each other under any coordinate transformation. It enables us to study different types of representations separately. In this section, we will focus on the transformation of type-V O(3) representations for the space group $P3$ as an illustrative example. As shown in Sec. II C in the main text, we need to consider six representations DTiDU$i\oplus$1, and PiPC$i\oplus$1 ($i = 1, 2, 3$), where 1 represents the identity irrep. The explicit representation matrices are given in Eq. (10) in the main text. The identity irrep is always invariant under any coordinate transformation. DTiDUi (PiPCi) is the direct sum of DTi (Pi) and its complex conjugate. Thus, it is sufficient to consider the transformation of the complex irreps DTi and Pi. The generators of allowable coordinate transformation consist of the generator of D_6 group, given as $\{6_{001}|\boldsymbol{0}\}$, $\{2_{100}|\boldsymbol{0}\}$,as well as the generators of origin shift, given as $\{1|1/3, 2/3, 0\}$, $\{1|2/3, 1/3, 0\}$, $\{1|0, 0, z\}$.

According to Eq. (18) in the main text, the momentum $\boldsymbol{k}$ of an irrep will be transformed to $V^{-1}\boldsymbol{k}$ under the action of $\{V|\boldsymbol{t}\}$. The line DT ($\boldsymbol{k} = (0, 0, v\pi)$) is invariant under the action of $V = 6_{001}, 2_{100}, 1$. Similarly, the line P ($\boldsymbol{k} = (2\pi/3, 2\pi/3, u\pi)$) is invariant under the action of

$V = 2_{100}$ and 1, and it is transformed to its TRS-partner line PC ($\boldsymbol{k} = (-2\pi/3, -2\pi/3, -v\pi)$) under $V = 6_{001}$. Therefore, DTi's and Pi's will not be transformed into each other. In table I, ρ and σ denote the irreps before and after the coordinate, respectively, and we show how $D_\sigma(\{3^+_{001}|\mathbf{0}\})$ is determined by ρ and coordinate transformation $\{V|\boldsymbol{t}\}$. Only $\{2_{100}|\mathbf{0}\}$ has a non-trivial effect on DTi's. It transforms DT2 and DT3 into each other while leaving DT1 invariant. We have also shown in Sec. II C in the main text that the real representation induced by DT2 and DT3 should be put in the same class because they can be continuously deformed to each other. Thus, DT1DU1 belongs to one class, and DT2DU2 and DT3DU3 are in the other class. For the irreps on the line P, we observe that $D_{\mathrm{P}i}(C_{3z})$ transforms to $e^{i2\pi/3}D_{\mathrm{P}i}(C_{3z})$ and $e^{i4\pi/3}D_{\mathrm{P}i}(C_{3z})$ under the action of $\{1|2/3, 1/3, 0\}$ and $\{1|1/3, 2/3, 0\}$, respectively (see the fourth and fifth rows of Table I). This implies that irrep P1 can be transformed into irreps P2 and P3, and hence these three irreps belong to the same class.

TABLE I. The transformation of C_{3z} under coordinate transformation $\{V|\boldsymbol{t}\}$. The irrep before the transformation is denoted as ρ (ρ = DTi, Pi, $i = 1, 2, 3$) with momentum $\boldsymbol{k}$, and σ denotes the irrep after the action of $\{V|\boldsymbol{t}\}$.

$\{V\|\boldsymbol{t}\}$	$\{V\|\boldsymbol{t}\}\{3^+_{001}\|\mathbf{0}\}\{V\|\boldsymbol{t}\}^{-1}$	$D_\sigma(C_{3z})$
$\{6_{001}\|\mathbf{0}\}$	$\{3^+_{001}\|\mathbf{0}\}$	$D_\rho(C_{3z})$
$\{2_{100}\|\mathbf{0}\}$	$\{3^-_{001}\|\mathbf{0}\}$	$(D_\rho(C_{3z}))^{-1}$
$\{1\|1/3, 2/3, 0\}$	$\{3^+_{001}\|1, 1, 0\}$	$e^{ik_1+ik_2}D_\rho(C_{3z})$
$\{1\|2/3, 1/3, 0\}$	$\{3^+_{001}\|1, 0, 0\}$	$e^{ik_1}D_\rho(C_{3z})$
$\{1\|0, 0, z\}$	$\{3_{001}\|\mathbf{0}\}$	$D_\rho(C_{3z})$

Details for the equivalence based on continuously connected wave vectors

To fully utilize the third equivalence based on continuously connected wave vectors, we can follow three steps. Firstly, if irreps are on the same high-symmetry line or plane or generic points, and they are labeled by the same symbol (*e.g.,* DT1 of $P3$ on different points on the DT line), they should be categorized into the same class. Secondly, a 2D real representation induced from non-HSP $\boldsymbol{k}$'s, which can be either $[\rho_{\boldsymbol{k}} \uparrow P]^c_1 \oplus [\rho^*_{\boldsymbol{k}} \uparrow P]^c_1$ or $[\rho_{\boldsymbol{k}} \uparrow P]^r_2$, should contain a pair of momenta $\pm\boldsymbol{k}$. If $\pm\boldsymbol{k}$ belongs to the same connected piece of the fix-point manifold of $P^{\boldsymbol{k}}$, they can be continuously moved to each other while remaining on this manifold. It is necessary to investigate whether this 2D real representation will be deformed into another one when the positions of $\pm\boldsymbol{k}$ are switched. For example, we find that DT2DU2 of $P3$ can be deformed into DT2DU3. Thirdly, suppose that the fixed point of $P^{\boldsymbol{k}}$ with $\boldsymbol{k}$ being a non-HSP is a n-dimensional ($n > 0$) manifold. Momentum in this manifold can continuously move within this manifold along the n independent tangent vectors and will return to its original position after completing a full winding around the first BZ. We need to study whether a 2D real representation will be deformed to another one after it momenta $\pm\boldsymbol{k}$ go through the process together, with $\pm\boldsymbol{k}$ moving in opposite directions.

Algorithm of modulo equivalences

To classify O(N) representations into different classes by equivalence relationship, the following algorithm can be utilized. This algorithm takes advantage of the transitivity property of the equivalence relation, and we only need to consider the generators of these equivalences. We start by placing the inequivalent O(N) representations in a given type into separate sets. Then, we successively apply the generators of the second and third equivalences to these representations. If an O(N) representation in one set can be transformed into a different representation in another set based on equivalence, we merge these two sets. Repeat the above process iteratively for all the generators. By following this algorithm, representations within the same set belong to the same class, indicating an equivalence, while those in different sets describe distinct SSGs.

C. ELECTRONIC BANDS IN SSG

d_{SBZ} in commuting SBZ

In this section, we study how SSG symmetries determine the dimension d_{SBZ} of the span of $\vec{S}(\tilde{\boldsymbol{k}})$ in SBZ. We have shown how to determine d_{SBZ} for collinear SSGs (Sec. III D in the main text), and we show the details on non-collinear SSGs where unitary translation generators $\hat{t}_{1,2,3}$ all commute with each other. As established in Sec. III D in the main text, d_{SBZ} are only determined by spin-rotation translations, generated by $\hat{t}_{1,2,3}$, and spin-rotation $\mathcal{PT}$ operation, denoted as $\hat{\mathcal{P}}\hat{\mathcal{T}}$. If $\hat{\mathcal{P}}\hat{\mathcal{T}}$ is present and $\boldsymbol{q}_{\mathcal{PT}} = 0$, $d_{\mathrm{SBZ}} = \dim[\bigcap_{i=1}^3 \ker(U_{t_i} - I) \bigcap \ker(U_{\mathcal{PT}} + I)]$; $d_{\mathrm{SBZ}} = \dim[\bigcap_{i=1}^3 \ker(U_{t_i} - I)]$ otherwise.

First, we will prove that if any of $\hat{t}_i$'s are accompanied by non-trivial spin rotations, they must share the same rotation axis. Without loss of generality, suppose that $U_{t_i} = U_{\boldsymbol{n}_i}(\theta_i)$ ($i = 1, 2$) with $\theta_i \in (0, 2\pi)$. In SSGs with commuting SBZ, $[\hat{t}_1, \hat{t}_2] = 0$ requires that $[e^{i\frac{\theta_1}{2}\boldsymbol{n}_1\cdot\boldsymbol{\sigma}}, e^{i\frac{\theta_2}{2}\boldsymbol{n}_2\cdot\boldsymbol{\sigma}}] = 0$. After some simple algebra, the equation is equivalent to $(\boldsymbol{n}_1 \times \boldsymbol{n}_2)\cdot\boldsymbol{\sigma} = 0$, where "$\times$" denotes the cross product. $\boldsymbol{n}_1$ should be parallel to $\boldsymbol{n}_2$. Thus, if any of U_{t_i} does not equal identity, $\dim[\bigcap_{i=1}^3 \ker(U_{t_i} - I)] = 1$.

Next, we investigate SSGs with $\mathcal{PT}$ symmetry and a non-trivial U_{t_i}. As the square of $\mathcal{PT}$ operation equals the identity, $U^2_{\mathcal{PT}} = I$, and $U_{\mathcal{PT}}$ can be either I or a π-rotation $U_{\boldsymbol{m}}(\pi)$. The group structure constrains the relationship between $U_{\mathcal{PT}}$ and $U_{t_i} = U_{\boldsymbol{n}}(\theta_i)$. As the conjugate of $\hat{t}_i$ under $\hat{\mathcal{P}}\hat{\mathcal{T}}$ is its inverse,

$$U^{-1}_{\mathcal{PT}} U_{\boldsymbol{n}}(\theta_i) U_{\mathcal{PT}} = U_{\boldsymbol{n}}(-\theta_i). \tag{S16}$$

Case (i): $U_{\mathcal{PT}} = I$. A non-zero θ_i must equal π. We notice

that

$$i\sigma_y\mathcal{K}e^{i\frac{\pi}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}\left(i\sigma_y\mathcal{K}\right)^{-1}=-e^{-i\frac{\pi}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}\,. \tag{S17}$$

Thus, in such a case, the SBZ is nonsymmorphic ($\tilde{\boldsymbol{q}}_{\mathcal{PT}}\neq 0$), and $d_{\rm SBZ}$ is only determined by U_{t_i}, and still equals 1. Case (ii): $U_{\mathcal{PT}}=U_{\boldsymbol{m}}(\pi)$. Eq. (S16) implies that $U_{U_{\boldsymbol{m}}(\pi)\boldsymbol{n}}(\theta_i)=U_{\boldsymbol{n}}(-\theta_i)$. Therefore, $U_{\boldsymbol{m}}(\pi)\boldsymbol{n}$ can equal either $\boldsymbol{n}$ or $-\boldsymbol{n}$. If $U_{\boldsymbol{m}}(\pi)\boldsymbol{n}=-\boldsymbol{n}$, which means that $\boldsymbol{m}\cdot\boldsymbol{n}=0$, θ_i's can take arbitrary values. One can verify that if $\boldsymbol{m}\cdot\boldsymbol{n}=0$,

$$i\sigma_y\mathcal{K}e^{i\frac{\pi}{2}\boldsymbol{m}\cdot\boldsymbol{\sigma}}e^{i\frac{\theta_i}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}e^{-i\frac{\pi}{2}\boldsymbol{m}\cdot\boldsymbol{\sigma}}\left(i\sigma_y\mathcal{K}\right)^{-1}=e^{-i\frac{\theta_i}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}\,. \tag{S18}$$

Thus, in such a case, the SBZ is symmorphic. $\mathcal{PT}$ constraints $\boldsymbol{S}(\tilde{\boldsymbol{k}})$ in a 2D plane perpendicular to $\boldsymbol{m}$, t_i constraint $\boldsymbol{S}(\tilde{\boldsymbol{k}})$ parallel to $\boldsymbol{n}$, which is a subspace of the 2D plane, resulting $d_{\rm SBZ}=1$. If $U_{\boldsymbol{m}}(\pi)\boldsymbol{n}=\boldsymbol{n}$, which means that $\boldsymbol{m}=\boldsymbol{n}$, non-zero θ_i's can only be π. One can verify that

$$i\sigma_y\mathcal{K}e^{i\frac{\pi}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}e^{i\frac{\pi}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}e^{-i\frac{\pi}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}\left(i\sigma_y\mathcal{K}\right)^{-1}=-e^{-i\frac{\pi}{2}\boldsymbol{n}\cdot\boldsymbol{\sigma}}\,. \tag{S19}$$

Thus, the SBZ is nonsymmorphic with this $U_{\mathcal{PT}}$, and $d_{\rm SBZ}$ is only determined by U_{t_i} and equals 1.

A coplanar magnetic model exhibiting $d_{\rm SBZ}=3$

We consider a 2D coplanar magnetic structure, whose crystalline symmetry is described by the space group P3 (No. 143) with lattice constant $c=\infty$. Three atoms, which are labeled by A, B, and C in Fig. S.1(a), exist in three C_{3z} invariant points $(0,0,0)$, $(2/3,1/3,0)$, and $(1/3,2/3,0)$ in the unit cell, respectively. The coplanar magnetic moments are localized around these atoms, given as

$$\boldsymbol{S}_A=(-\frac{1}{2},\frac{\sqrt{3}}{2},0),\ \boldsymbol{S}_B=(0,-1,0),\ \boldsymbol{S}_C=(1,0,0)\,. \tag{S20}$$

The magnetic structure [Fig. S.1(a)] remains invariant under operations $\{I|3^+_{001}|\boldsymbol{0}\}$ and $\{I|1|\boldsymbol{a}_i\}$ $(i=1,2)$, and hence is described by the SSG P143.1.1 GM1.

We consider an electronic Hamiltonian in this magnetic structure, given as

$$\mathcal{H}=t\sum_{\langle R,\alpha;R',\alpha'\rangle}c^\dagger_{R,\alpha}\sigma_0 c_{R',\alpha'}+J\sum_{R,\alpha}\boldsymbol{S}_\alpha\cdot\boldsymbol{s}_{R,\alpha}, \tag{S21}$$

with

$$\boldsymbol{s}^\mu_{R,\alpha}=\frac{1}{2}c^\dagger_{R,\alpha}\sigma_\mu c_{R,\alpha}\quad(\mu=x,y,z)$$

being the spin operator of the electrons. Here $c^\dagger_{R,\alpha}=(c^\dagger_{R,\alpha,\uparrow},c^\dagger_{R,\alpha,\downarrow})$ $(\alpha=A,B,C)$ is a two-component spin-1/2 electron creation operator in the unit cell R, sub-lattice α. The first term of the Hamiltonian represents nearest-neighboring hopping, represented by the bonds in Fig. S.1 (a). The hopping matrix is proportional to σ_0 because the SOC is considered negligible. The second term describes the on-site interaction between the conduction electron and localized magnetic moments $\boldsymbol{S}_{R,\alpha}$.

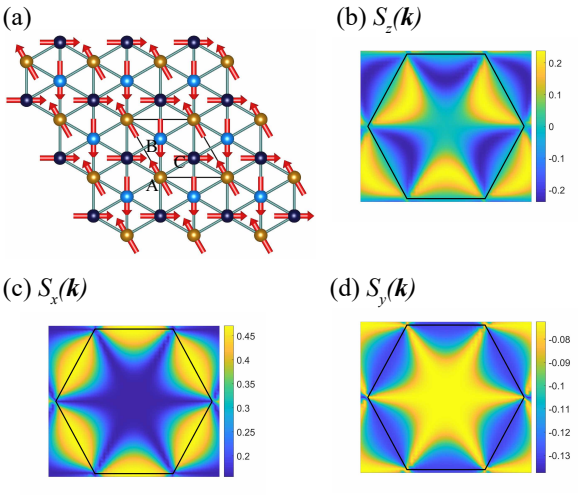

FIG. S.1. (a) Coplanar magnetic structure with SSG P143.1.1 GM1. (b)-(d) The z [(b)], x [(c)], y [(d)] components of the spin expectation values of the Bloch states in the lowest band. The colors (see the color bar) represent the values. The hexagon is the boundary of the first BZ.

We choose parameters as $t=1$, $J=-1$, and study the spin texture $\vec{S}(\boldsymbol{k})$ in the momentum space. Since in this SSG, all translations are accompanied by the identity spin operations, the magnetic BZ and SBZ coincide. Figs. S.1(b)-(d) show the expectation values $\vec{S}(\boldsymbol{k})$ of spin operators for the Bloch states in the lowest energy band. Although $\int_{\rm BZ}S_z(\boldsymbol{k})d\boldsymbol{k}=0$, $S_z(\boldsymbol{k})$ is non-zero at individual $\boldsymbol{k}$ [Fig. S.1(b)]. For generic $\boldsymbol{k}$, $S_x(\boldsymbol{k})$ and $S_y(\boldsymbol{k})$ are also non-zero, leading to $d_{\rm SBZ}=d_{\rm BZ}=3$, consistent with our theoretical analysis (Table IV in the main text).

Algorithm for determining whether an SBZ is symmorphic or nonsymmorphic

In this section, we present the detailed algorithm for determining whether an SBZ of a collinear SSG with $[\hat{t}_i,\hat{t}_j]=0\,(i,j=1,2,3)$ is symmorphic or nonsymmorphic. In Sec. III C in the main text, we have shown the SSG momentum $\tilde{\boldsymbol{k}}$ is transformed to $s_gR_g\tilde{\boldsymbol{k}}+\tilde{\boldsymbol{q}}_g$ under a generic SSG operation $\hat{g}$, where $s_g=1$ (-1) if g is unitary (anti-unitary), and have also explained how to determine the value of $\tilde{\boldsymbol{q}}_g$. To determine whether an SBZ is symmorphic or nonsymmorphic, we need to find out whether a $\boldsymbol{\theta}$ exists such that

$$-s_g\boldsymbol{\theta}+R_g\boldsymbol{\theta}\equiv\tilde{\boldsymbol{q}}_g \tag{S22}$$

holds for all $g\in\mathcal{G}$. Since operations in the unitary translation group T_U leave $\tilde{\boldsymbol{k}}$ invariant, we only need to consider the action of the coset representatives $g_1,g_2,\cdots,g_N$ of $\mathcal{G}/T_U$.

To proceed, we write the matrix R_g and vectors $\tilde{\boldsymbol{q}}_g$ on the basis of reciprocal lattice vectors $\boldsymbol{b}_i$'s. $R_g\boldsymbol{b}_i$ can be written as $\sum_{j=1}^3\boldsymbol{b}_jM_{g;ji}$, where $M_{g;ji}$ are integers since the spatial operations must be compatible with the lattice vectors. As

shown in Sec. III C in the main text, the component of $\tilde{\boldsymbol{q}}_g$ must be a half-integer on the basis of $\boldsymbol{b}_i$'s, We can construct a $3N \times 3$ matrices A and a $3N \times 1$ vector Q

$$C = \begin{pmatrix} M_{g_1} - s_{g_1} I \\ \vdots \\ M_{g_N} - s g_N I \end{pmatrix}, \quad Q = \begin{pmatrix} \tilde{\boldsymbol{q}}_{g_1} \\ \vdots \\ \tilde{\boldsymbol{q}}_{g_N} \end{pmatrix}. \tag{S23}$$

With this construction, solving Eq. (S22) is equivalent to finding a $\boldsymbol{\theta}$ such that $C\boldsymbol{\theta} - Q$ is an integer vector. A necessary condition of $C\boldsymbol{\theta} - Q$ being an integer vector is that $2C\boldsymbol{\theta}$ is an integer vector because $2Q$ is an integer matrix. To find all vectors $\boldsymbol{\theta}$ satisfying $2C\boldsymbol{\theta}$ being an integer vector, we can apply the Smith decomposition to the matrix $2C$, given as:

$$2C = SAT\,, \tag{S24}$$

where S, A, T are $3N \times 3N$, $3N \times 3$, and 3×3 integer matrices, respectively. Matrix A is diagonal, given as

$$A = \begin{pmatrix} \alpha_1 & 0 & 0 \\ 0 & \alpha_2 & 0 \\ 0 & 0 & \alpha_3 \\ 0 & 0 & 0 \\ \vdots & \vdots & \vdots \\ 0 & 0 & 0 \end{pmatrix}, \tag{S25}$$

and the diagonal elements are non-negative integers that satisfy that α_{i+1} being divisible by α_i $(i = 1, 2)$. Some of α_i can be zero, and without loss of generality, we assume that $\alpha_j > 0\,(j \le r \le 3)$ and $\alpha_j = 0\,(j > r)$. S and T satisfy that $|\det(S)| = |\det(T)| = 1$, which means that S^{-1} and T^{-1} are also integer matrices. Thus, the condition for $2C\boldsymbol{\theta} = SAT\boldsymbol{\theta}$ being an integer vector is equivalent to $AT\boldsymbol{\theta}$ being an integer vector. If $AT\boldsymbol{\theta}$ is an integer vector, $AT\boldsymbol{\theta}$ must be in the form

$$AT\boldsymbol{\theta} = \begin{pmatrix} m_1 \\ \vdots \\ m_r \\ 0 \\ \vdots \\ 0 \end{pmatrix} \text{ with } m_i \in \mathbb{Z}\,(i \le r). \tag{S26}$$

We then need to determine whether an $AT\boldsymbol{\theta}$ of this form can satisfy $S(\frac{1}{2}AT\boldsymbol{\theta}) - Q$ to be an integer vector. Enumerating all integers m_i is unnecessary because if m_i's are all even, $S(\frac{1}{2}AT\boldsymbol{\theta})$ must be an integer matrix. Thus, we only need to test the cases $m_i \in \{0, 1\}$. If there exist $m_1, \cdots, m_r$ that satisfy $S(\frac{1}{2}AT\boldsymbol{\theta}) - Q$ to be an integer vector, the SBZ is symmorphic, and $\boldsymbol{\theta}$ is given by

$$\boldsymbol{\theta} = T^{-1} \begin{pmatrix} m_1/\alpha_1 \\ \vdots \\ m_r/\alpha_r \\ \vdots \\ 0 \end{pmatrix}. \tag{S27}$$

Otherwise, the SBZ is nonsymmorphic.

Energy bands in non-commuting SBZ

In this section, we investigate the electron bands in the SSG N143.16.1 M1. This SSG can be generated by $\hat{t}_1 = \{\sigma_y|1|\boldsymbol{a}_1\}$, $\hat{t}_2 = \{\sigma_x|1|\boldsymbol{a}_2\}$, $\hat{t}_3 = \{\sigma_0|1|\boldsymbol{a}_2\}$, and $\hat{C}_{3z} = \{e^{i\frac{\pi}{3}\boldsymbol{n}\cdot\boldsymbol{\sigma}}|3^+_{001}|\boldsymbol{0}\}$ with $\boldsymbol{n} = \frac{\sqrt{3}}{3}(\boldsymbol{e}_x + \boldsymbol{e}_y + \boldsymbol{e}_z)$. Note that in Sec. III A in the main text, $\hat{U}_{t_1}$, $\hat{U}_{t_2}$ are chosen as $i\sigma_y$, $i\sigma_z$. Compared to that, we apply a gauge transformation, which can simplify the form of the transformation of SSG momentum. Bloch states are defined by using the eigenvalues of the commuting operators $\hat{t}_1$, $\hat{t}_2^2$, and $\hat{t}_3$, as shown in Eq. (37) in the main text. Let us consider the action of $\hat{C}_{3z}$ on the Bloch states. In Sec. III C 2 in the main text, we showed $|\psi(\tilde{\boldsymbol{k}})\rangle$ and $\hat{t}_2\,|\psi(\tilde{\boldsymbol{k}})\rangle$ share the same energy $E(\tilde{\boldsymbol{k}})$, Thus, their linear combination is also an eigenstate with energy $E(\tilde{\boldsymbol{k}})$. Let $|\phi_\pm\rangle = |\psi(\tilde{\boldsymbol{k}})\rangle \pm e^{-i(\tilde{k}_2+\pi)/2}\hat{t}_2\,|\psi(\tilde{\boldsymbol{k}})\rangle$, and we will prove $\hat{C}_{3z}\,|\phi\rangle$ is an Bloch state. We can verify that $\hat{C}_{3z}^{-1}\hat{t}_1\hat{C}_{3z} = i\hat{t}_1^{-1}\hat{t}_2^{-1}$, $\hat{C}_{3z}^{-1}\hat{t}_2^2\hat{C}_{3z} = \hat{t}_1^2$, and $\hat{C}_{3z}^{-1}\hat{t}_1\hat{C}_{3z} = \hat{t}_3$ Then,

$$\begin{aligned} &\hat{C}_{3z}^{-1}\hat{t}_1\hat{C}_{3z}\,|\phi_\pm\rangle \\ &= i\hat{t}_1^{-1}\left(\pm e^{-i(\tilde{k}_2+\pi)/2}\,|\psi(\tilde{\boldsymbol{k}})\rangle + \hat{t}_2\hat{t}_2^{-2}\,|\psi(\tilde{\boldsymbol{k}})\rangle\right) \\ &= i\hat{t}_1^{-1}\left(\pm e^{-i(\tilde{k}_2+\pi)/2}\,|\psi(\tilde{\boldsymbol{k}})\rangle + \hat{t}_2 e^{-i\tilde{k}_2}\,|\psi(\tilde{\boldsymbol{k}})\rangle\right) \\ &= \pm e^{-i(2\tilde{k}_1+\tilde{k}_2)/2}\,|\psi(\tilde{\boldsymbol{k}})\rangle + \hat{t}_2 e^{-i\tilde{k}_2 - i\tilde{k}_1 - i\pi/2}\,|\psi(\tilde{\boldsymbol{k}})\rangle \\ &= \pm e^{-i(2\tilde{k}_1+\tilde{k}_2)/2}\,|\phi_\pm\rangle\,. \end{aligned} \tag{S28}$$

In this derivation, we utilize the fact that $\hat{t}_2\,|\psi(\tilde{\boldsymbol{k}})\rangle$ is a Bloch state with SSG momentum $\tilde{\boldsymbol{k}} + \frac{1}{2}\boldsymbol{b}_1$. Similarly, we can show that $\hat{C}_{3z}^{-1}\hat{t}_2^2\hat{C}_{3z}\,|\phi_\pm\rangle = e^{2\tilde{k}_1}\,|\phi_\pm\rangle$ and $\hat{C}_{3z}^{-1}\hat{t}_3\hat{C}_{3z}\,|\phi_\pm\rangle = e^{\tilde{k}_3}\,|\phi_\pm\rangle$. Thus, the $\hat{C}_{3z}\,|\phi_+\rangle$ ($|\phi_-\rangle$) is a Bloch state with SSG momentum $\tilde{\boldsymbol{k}}' = \tilde{k}_1'\boldsymbol{b}_1 + \tilde{k}_2'\frac{1}{2}\boldsymbol{b}_2 + \tilde{k}_3'\boldsymbol{b}_3$, where $\tilde{k}_1' = -(2\tilde{k}_1 + \tilde{k}_2)/2$ $\left(\tilde{k}_1' = -(2\tilde{k}_1 + \tilde{k}_2 + 2\pi)/2\right)$, $\tilde{k}_2' = 2\tilde{k}_1$, and $\tilde{k}_3' = 2\tilde{k}_3$. The momenta after tranformation can also be written as $\tilde{\boldsymbol{k}}'$ are $R_{\boldsymbol{z}}(2\pi/3)\tilde{\boldsymbol{k}}$ $\left(R_{\boldsymbol{z}}(2\pi/3)\tilde{\boldsymbol{k}} + \frac{1}{2}\boldsymbol{b}_1\right)$.

D. MORE DISCUSSIONS ON THE MAGNETIC MATERIALS

Identification of SSGs for magnetic materials

In this section, we summarize how to find the SSG (or qSSG) of a crystalline magnetic structure. We will first show an algorithm that can find all possible O(3) matrices O that can produce the map

$$O\boldsymbol{S}_{P_i} = \boldsymbol{S}_i \quad (i = 1, 2, \cdots, N)\,, \tag{S29}$$

given a finite number of magnetic moments $\boldsymbol{S}_1, \cdots, \boldsymbol{S}_N$ and their permutation $\boldsymbol{S}_{P_1}, \cdots, \boldsymbol{S}_{P_N}$. As discussed in Sec. II A in the main text, in the case that $\boldsymbol{S}_i$'s are non-co-planar, if O exists, it must be unique. For the coplanar (*e.g.,* along the

x, y plane) and collinear (*e.g.,* along the z direction) cases, O must be diagonal in the form $\mathrm{diag}\,(O_{xy}, O_z)$. Meanwhile, only O_{xy} (O_z) influences the transformation in the coplanar (collinear) case, and if O_{xy} (O_z) exists, it must be unique. Thus, we only need to find an O(2) (O(1)) matrix O_{xy} (O_z) if $\boldsymbol{S}_i$'s are coplanar (collinear).

For the non-coplanar case, without loss of generality, we assume that $\boldsymbol{S}_1, \boldsymbol{S}_2, \boldsymbol{S}_3$ are linearly independent. The only 3×3 matrix $\mathcal{V}$ that can transform linearly independent vectors $\boldsymbol{S}_1, \boldsymbol{S}_2, \boldsymbol{S}_3$ to $\boldsymbol{S}_{P_1}, \boldsymbol{S}_{P_2}, \boldsymbol{S}_{P_3}$ is given by

$$\mathcal{V} = (\boldsymbol{S}_{P_1},\, \boldsymbol{S}_{P_2},\, \boldsymbol{S}_{P_3})\,(\boldsymbol{S}_1,\, \boldsymbol{S}_2,\, \boldsymbol{S}_3)^{-1}\ . \tag{S30}$$

If $\mathcal{V} \in \mathrm{O}(3)$, *i.e.,* $\mathcal{V}\mathcal{V}^T = I$ and $\mathcal{V}\boldsymbol{S}_{P_i} = \boldsymbol{S}_i$ is satisfied for all $i > 3$, we can choose the unique O(3) matrix $O = \mathcal{V}$. Otherwise, no O(3) matrix can satisfy Eq. (S29). For the coplanar case, without loss of generality, we assume that $\boldsymbol{S}_1, \boldsymbol{S}_2$ are linearly independent. The unique 2×2 matrix $\mathcal{V}$ that can transform linearly independent vectors $\boldsymbol{S}_1, \boldsymbol{S}_2$ to $\boldsymbol{S}_{P_1}, \boldsymbol{S}_{P_2}$ is given by

$$\mathcal{V}_{xy} = (\boldsymbol{S}_{P_1},\, \boldsymbol{S}_{P_2})\,(\boldsymbol{S}_1,\, \boldsymbol{S}_2)^{-1}\ , \tag{S31}$$

where $\boldsymbol{S}_i$ and $\boldsymbol{S}_{P_i}$ $(i = 1, 2)$ have zero z component and are written as 2×1 column vector. If $\mathcal{V}_{xy} \in \mathrm{O}(2)$, and $\mathcal{V}_{xy}\boldsymbol{S}_{P_i} = \boldsymbol{S}_i$ is satisfied for all $i > 2$, we can choose the unique O(2) matrix $O_{xy} = \mathcal{V}_{xy}$. Otherwise, Eq. (S29) cannot be satisfied. For the collinear case, if $\boldsymbol{S}_{P_i} = \boldsymbol{S}_i$ ($\boldsymbol{S}_{P_i} = -\boldsymbol{S}_i$) is satisfied for all i, $O_z = 1$ (-1). Otherwise, Eq. (S29) cannot be satisfied.

Then, we present the detailed algorithm for finding the SSG of a magnetic structure. Here, we use a non-coplanar magnetic structure as an example. The algorithm for the coplanar (collinear) cases is very similar, and the only difference is that a spin operation is represented by an O(2) (O(1)) matrix but not an O(3) matrix.

1. Find the space group G_{latt} of the crystalline structure without the magnetic moments. Let $\boldsymbol{a}_{L1}, \boldsymbol{a}_{L2}, \boldsymbol{a}_{L3}$ be the lattice vectors of G_{latt}, and T_{latt} be the translation subgroup of G_{latt}.

2. Find the lattice vectors $\boldsymbol{a}_{M1}, \boldsymbol{a}_{M2}, \boldsymbol{a}_{M3}$ of magnetic unit cell. A finite number of magnetic moments $\boldsymbol{S}(\boldsymbol{r}_1), \cdots, \boldsymbol{S}(\boldsymbol{r}_N)$ exist in a magnetic unit cell, and the magnetic moments satisfy $\boldsymbol{S}(\boldsymbol{r}_i) = \boldsymbol{S}(\boldsymbol{r}_i + \boldsymbol{a}_{Mj})$ $(i \le N, j \le 3)$, and translations along the $\boldsymbol{a}_{Mi}$'s generates a subgroup T_M of the translation group T.

3. Some spatial rotation in G_{latt} is not compatible with $\boldsymbol{a}_{Mi}$'s, *i.e.,* cannot be written as an integer matrix in their lattice coordinate. Only spatial operations compatible with $\boldsymbol{a}_{Mi}$'s can belong to the parent space group of the SSG (see proof in the end of this section), and these spatial operations form a subgroup P_{latt} of G_{latt}. Let $p_1, p_2, \cdots, p_m$ be the coset representatives of the quotient group P_{latt}/T_M.

4. After the spatial operation p_j, the magnetic moments in the position $\boldsymbol{r}_1, \cdots, \boldsymbol{r}_N$ are $\boldsymbol{S}(p_j^{-1}\boldsymbol{r}_1), \cdots, \boldsymbol{S}(p_j^{-1}\boldsymbol{r}_N)$, which are a permutation of $\boldsymbol{S}(\boldsymbol{r}_1), \cdots, \boldsymbol{S}(\boldsymbol{r}_N)$. Using the algorithm introduced above, we can determine whether an O(3) matrix O satisfying $O\boldsymbol{S}(g_j^{-1}\boldsymbol{r}_i) = \boldsymbol{S}(\boldsymbol{r}_i)\,\forall i \le N$ exists and find its value if O exists. Suppose for operation $p_{i_1}, p_{i_2}, \cdots, p_{i_n}$ $(n \le m)$, the O(3) matrix satisfying the condition exists and are given as $O_{p_{i_1}}, \cdots, O_{p_{i_n}}$.

5. Up to now, we obtain the parent space group of P the SSG, which are the union of these cosets

$$p_{i_1}T_M,\, p_{i_2}T_M,\, \cdots,\, p_{i_n}T_M\ . \tag{S32}$$

The spin operations in each coset are the same, which are

$$O_{p_1}, O_{p_2}, \cdots, O_{p_n}\ , \tag{S33}$$

respectively. Note that some of $p_{i_1}, p_{i_2}, \cdots, p_{i_n}$ might be translation operations with a non-trivial spin operation.

These spin operations, which are represented by O(N) ($N = 1, 2, 3$) matrices, form a representation of the parent space group. When classifying SSGs, we categorize O(N) representations into different types by the constituent irreps, and the nomenclature of SSGs is also based on the irreps. Thus, to know the specific SSG that the O(N) representation corresponds to, we should decompose the O(N) representations into irreps. To this end, we identify the momenta of the representation by studying the representation matrices of translations. Let $\boldsymbol{a}_i$ $(i = 1, 2, 3)$ be the lattice vectors of the parent space group, and $O_{\boldsymbol{a}_i}$'s be their representation matrices. $O_{\boldsymbol{a}_i}$'s must commute with each other, because $O_{\boldsymbol{a}_i}O_{\boldsymbol{a}_j}$ and $O_{\boldsymbol{a}_j}O_{\boldsymbol{a}_i}$ both equal the representation matrix of $\{1|\boldsymbol{a}_i + \boldsymbol{a}_j\}$. Thus, $O_{\boldsymbol{a}_i}$'s $(i = 1, 2, 3)$ share a set of common eigenvectors $|v_j\rangle$ $(j = 1, \cdots, N)$: $O_{\boldsymbol{a}_i}\,|v_j\rangle = e^{i2\pi\lambda_{ij}}\,|v_j\rangle$ $(\lambda_{ij} \in [0, 1))$. The jth $(j \le N)$ momentum is given by $\boldsymbol{k}_j = \sum_{i=1}^{3} \boldsymbol{b}_i\lambda_{ij}$, where $\boldsymbol{b}_j$ satisfying $\boldsymbol{a}_i \cdot \boldsymbol{b}_j = 2\pi\delta_{i,j}$ is the reciprocal lattice vector. After knowing the momenta $\boldsymbol{k}_j$, we can reduce the O(N) representations to the allowable representation $\rho_{\boldsymbol{k}_j}$ of the little group $P^{\boldsymbol{k}_j}$ of $\boldsymbol{k}_j$. Note that "allowable" means that translation $\{1|\boldsymbol{v}\}$ is represented by $e^{i\boldsymbol{k}_j\cdot\boldsymbol{v}}I$. Suppose that T is the translation subgroup of the parent space group, and the little group of $P^{\boldsymbol{k}_j}$ consists of $p'_1T, p'_2T, \cdots, p'_{n'}T$, and the O($N$) representation matrix of p'_i is $O_{p'_i}$. The representation matrix $D_{\rho_{\boldsymbol{k}_j}}(p'_i)$ of p'_i in $\rho_{\boldsymbol{k}_j}$ should be given by $Q_{\boldsymbol{k}_j}O_{p'_i}Q_{\boldsymbol{k}_j}$, where $Q_{\boldsymbol{k}_j} = \sum_{i\le N, \boldsymbol{k}_i=\boldsymbol{k}_j} |v_i\rangle\,\langle v_i|$ is the projection operator to the eigenspace of the momentum $\boldsymbol{k}_j$. Knowing the little group representation $\rho_{\boldsymbol{k}_j}$, we can easily reduce it to the irreps of $P^{\boldsymbol{k}}$ with the character theory. Repeating this process for all $\boldsymbol{k}_j$, we can reduce the O(N) representation to the irreps of the little groups and hence determine which SSG it corresponds to.

In the following, we will prove that the spatial-rotation part R_g of an SSG operation $g \in \mathcal{G}$ must be compatible with lattice vectors $\boldsymbol{a}_{Mi}$'s of pure translation subgroup $T_M = \{\{I|1|\boldsymbol{v}\}\,|\,\{I|1|\boldsymbol{v}\} \in \mathcal{G}\}$. If $t = \{I|1|\boldsymbol{v}\} \in T_M$, $\boldsymbol{v}$ must be in the form $\sum_i^3 m_i\boldsymbol{a}_{Mi}$ with $m_i \in \mathbb{Z}$. The conjugate operation of $t = \{I|R|\boldsymbol{v}\}$ under a generic SSG operation

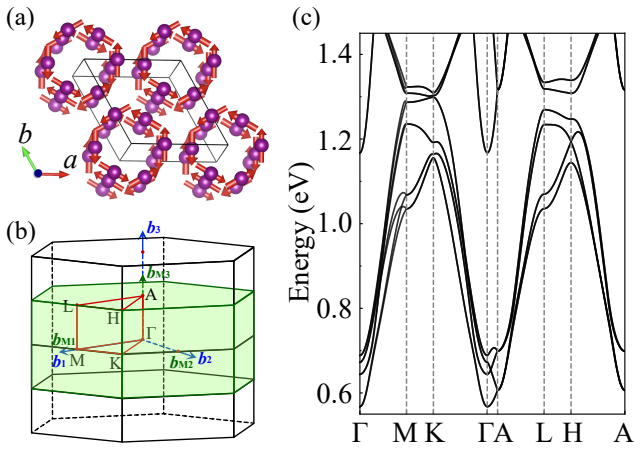

FIG. S.2. (a) The magnetic structure of $InMnO_3$ showing only the magnetic atoms (Mn). (b)The first BZs in the SSG reciprocal lattice $\boldsymbol{b}_i$'s (black lines) and MSG reciprocal lattice $\boldsymbol{b}_{Mi}$'s (green region). (c) The first-principle calculation energy bands.

$g = \{X_g U_g | R_g | \boldsymbol{v}_g\}$ is $g^{-1}tg = \{I|1|R_g^{-1}\boldsymbol{v}\}$, which still belongs to T_M. Thus, for any R_g, $R_g^{-1}\boldsymbol{v}$ must be in the form $\sum_i^3 m_i' \boldsymbol{a}_{Mi}$ with $m_i' \in \mathbb{Z}$, and it is the definition of rotation being compatible with lattice vectors.

Nonsymmorphic SBZ in $InMnO_3$

$InMnO_3$ (No. 1.525) has a hexagonal lattice structure. Let $\boldsymbol{a}_1, \boldsymbol{a}_2, \boldsymbol{a}_3$ be its lattice vectors along the three directions. In the magnetic phase, the spin moments lie in the x, y plane [2]. In each layer along the z direction, spins form a triangular antiferromagnetic structure, and spin moments related by lattice translation $\{1|\boldsymbol{a}_3\}$ have opposite directions. The MSG of this structure is $P_{2c}31m'$ (No. 157.5.1288). The magnetic unit cell is twice that in the paramagnetic phase, in which the MSG lattice vectors $\boldsymbol{a}_{M1,M2} = \boldsymbol{a}_{1,2}$, and $\boldsymbol{a}_{M3} = 2\boldsymbol{a}_3$. Fig. S.2(c) shows the energy bands obtained from the first-principle calculation. These bands are plotted in the BZ of the MSG, and the high symmetry points in MSG BZ are labeled in Fig. S.2(b). They exhibit the following features that MSG cannot explain: (i) Along the line Γ-K-M, the bands are two-fold degenerate. However, the little co-group of the MSG along this line is the point group m, which only has two 1D coirreps. (ii) At points A and H, the degree of degeneracy is either two or four. The little co-group of the MSG on A is $3m1'$ (the direct product point group $3m$ and Z_2^T TRS group), and the little co-group on H is $3m$. Both of them only have two 1D coirreps and one 2D coirrep. (iii) The bands are at least two-fold degenerate along the path A-L-H-A. However, the little co-groups on A-L and L-H-A are m' (the Z_2^T group generated by the joint operation of mirror and time-reversal) and m, respectively, either of which only has a 1D coirrep.

The SSG of this structure is P157.6.2 A3, whose parent space group is $P3m1$. The SSG shares the same lattice vectors $\boldsymbol{a}_i$'s as the space group in the paramagnetic phase. Table II shows the generators of this SSG and how an SSG momentum $\tilde{\boldsymbol{k}}$ is transformed under these operations. The mirror operation $\hat{M}_{\boldsymbol{n}_{1\bar{1}0}} = \{\boldsymbol{n}_{1\bar{1}0}\cdot\boldsymbol{\sigma}|m_{1\bar{1}0}|\boldsymbol{0}\}$ ($\boldsymbol{n}_{1\bar{1}0} = \sqrt{3}/2\boldsymbol{e}_x - 1/2\boldsymbol{e}_y$) acts a glide operation on the $\tilde{\boldsymbol{k}}$. Therefore, the SBZ is nonsymmorphic. Before investigating the energy bands in the SBZ, we study the relationship between SSG and crystal momentum. Within our choice of spin rotation (see the first two rows of Table II), translations $\{1|\sum_{i=1}^3 m_i\boldsymbol{a}_{Mi}\}$ are always accompanied by σ_0 without an extra phase. Thus, the crystal momentum $\boldsymbol{k}$ equals the SSG momentum $\tilde{\boldsymbol{k}}$. On the other hand, the first SSG BZ is twice as large as the magnetic BZ, and $\boldsymbol{b}_3 = 2\boldsymbol{b}_{M3}$, indicating that SSG momenta $\tilde{\boldsymbol{k}}$ and $\tilde{\boldsymbol{k}} + 1/2\boldsymbol{b}_3$ are considered as equivalent in the magnetic BZ. Then, we study the symmetries of different $\tilde{\boldsymbol{k}}$. Let $\tilde{\boldsymbol{k}}_{\Gamma-\mathrm{K}} = u\boldsymbol{b}_1 + u\boldsymbol{b}_2$ with $u \in [0,1)$. $\hat{M}_{\boldsymbol{n}_{1\bar{1}0}}$ transforms $\tilde{\boldsymbol{k}}_{\Gamma-\mathrm{K}}$ to $\tilde{\boldsymbol{k}}'_{\Gamma-\mathrm{K}} = \tilde{\boldsymbol{k}}_1 + \frac{1}{2}\boldsymbol{b}_1$, implying that $E_n(\tilde{\boldsymbol{k}}_{\Gamma-\mathrm{K}}) = E_n(\tilde{\boldsymbol{k}}'_{\Gamma-\mathrm{K}})$ in the SBZ. Similarly, $\hat{M}_{\boldsymbol{n}_{1\bar{1}0}}\hat{C}_{3z}$ ($\hat{C}_{3z} = -\{e^{i\frac{\pi}{3}\sigma_z}|3^+_{001}|\boldsymbol{0}\}$) transforms $\tilde{\boldsymbol{k}}_{\mathrm{K}-\mathrm{M}} = (1/3+v)\boldsymbol{b}_1 + (1/3-2v)\boldsymbol{b}_2$ with $v \in [0, 1/6]$ to $\tilde{\boldsymbol{k}}_{\mathrm{K}-\mathrm{M}} + 1/2\boldsymbol{b}_3$. After folding the band, this symmetry explains the feature (i) in the magnetic BZ. Let $\tilde{\boldsymbol{k}}_{\mathrm{A}} = \frac{1}{4}\boldsymbol{b}_3 = \frac{1}{2}\boldsymbol{b}_{M3}$, $\tilde{\boldsymbol{k}}_{\mathrm{H}} = \frac{1}{3}(\boldsymbol{b}_1+\boldsymbol{b}_2)+\frac{1}{4}\boldsymbol{b}_3$. Both $\tilde{\boldsymbol{k}}_{\mathrm{A}}$ and $\tilde{\boldsymbol{k}}_{\mathrm{H}}$ have the symmetries $\hat{\mathcal{T}} = \{TU_{\boldsymbol{z}}(\pi)|1|\boldsymbol{0}\}$ and $\hat{C}_{3z}$. The little co-groups of the SSG at $\tilde{\boldsymbol{k}}_{\mathrm{A,H}}$ have one 1D coirrep ($D(\hat{C_{3z}}) = 1$) and one 2D coirrep ($D(\hat{C}_{3z}) = \mathrm{diag}(e^{i\frac{2\pi}{3}}, e^{i\frac{4\pi}{3}})$). Due to $\hat{M}_{\boldsymbol{n}_{1\bar{1}0}}$, $E_n(\tilde{\boldsymbol{k}}_{\mathrm{A,H}}) = E_n(\tilde{\boldsymbol{k}}_{\mathrm{A,H}} + \frac{1}{2}\boldsymbol{b}_3)$. The feature (ii) in the magnetic BZ has been successfully explained. Let $\tilde{\boldsymbol{k}}_{\mathrm{A}-\mathrm{L}} = w\boldsymbol{b}_1 + \frac{1}{4}\boldsymbol{b}_3$ with $w \in [0,1)$. $\hat{\mathcal{T}}\hat{M}_{\boldsymbol{n}_{1\bar{1}0}}\hat{C}_{3z}$ transforms $\tilde{\boldsymbol{k}}_{\mathrm{A}-\mathrm{L}}$ to $\tilde{\boldsymbol{k}}'_{\mathrm{A}-\mathrm{L}} = w\boldsymbol{b}_1 - \frac{1}{4}\boldsymbol{b}_3$. Note that $\tilde{\boldsymbol{k}}_{\mathrm{A}-\mathrm{L}}$ and $\tilde{\boldsymbol{k}}'_{\mathrm{A}-\mathrm{L}}$ differ by $\frac{1}{2}\boldsymbol{b}_1$ and hence correspond to the same point in the magnetic BZ. This explains the two-fold degeneracy on the line A-L in magnetic BZ. The two-fold-degeneracy on the L-H-A can be explained in the same manner as we adopted for the line Γ-K-M.

TABLE II. The generators of the SSG (P157.6.2 A3) of coplanar magnetic material $InMnO_3$. The last row is for the pure-spin-operation group $\mathcal{S}$. The last column shows how the SSG momentum is transformed under the SSG operations. In the forth row, $\boldsymbol{n}_{1\bar{1}0} = \sqrt{3}/2\boldsymbol{e}_x - 1/2\boldsymbol{e}_y$.

SSG operation	Spin operations on electrons	Transformation of SSG momentum $\tilde{\boldsymbol{k}}$
$\{I\|1\|\boldsymbol{a}_{1,2}\}$	σ_0	$\tilde{\boldsymbol{k}}$
$\{U_{\boldsymbol{z}}(\pi)\|1\|\boldsymbol{a}_3\}$	σ_z	$\tilde{\boldsymbol{k}}$
$\{U_{\boldsymbol{z}}(\frac{2\pi}{3})\|3^+_{001}\|\boldsymbol{0}\}$	$-e^{i\frac{\pi}{3}\sigma_z}$	$R_{\boldsymbol{z}}(\frac{2\pi}{3})\tilde{\boldsymbol{k}}$
$\{U_{\boldsymbol{x}}(\pi)\|m_{1\bar{1}0}\|\boldsymbol{0}\}$	$\boldsymbol{n}_{1\bar{1}0}\cdot\boldsymbol{\sigma}$	$-R_{\boldsymbol{n}_{1\bar{1}0}}(\pi)\tilde{\boldsymbol{k}} + \frac{1}{2}\boldsymbol{b}_3$
$\{TU_{\boldsymbol{z}}(\pi)\|1\|\boldsymbol{0}\}$	$\sigma_x\mathcal{K}$	$-\tilde{\boldsymbol{k}} + \frac{1}{2}\boldsymbol{b}_3$

Extra band degeneracy in non-coplanar Mn_3Ge

We use Mn_3Ge (No. 0.203) in a non-coplanar magnetic structure as an example to show that SSGs can explain the extra degeneracy of electron bands in non-coplanar magnetism.

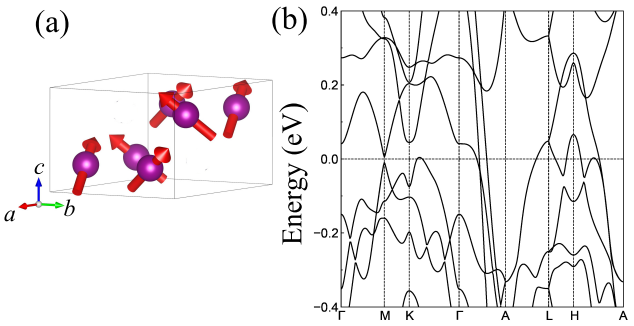

FIG. S.3. (a) The non-coplanar magnetic structure of Mn_3Ge showing only the magnetic atoms (Mn). (b) The first-principle calculation energy bands.

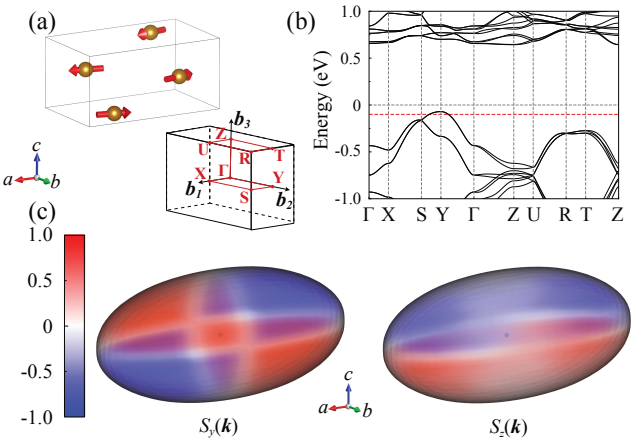

FIG. S.4. (a) Upper left: the magnetic structure of $FePO_4$ showing only the magnetic atoms (Fe). Bottom right: the BZ of $FePO_4$. (b) The first-principle energy bands of $FePO_4$ along the path in the BZ shown in subfigure (a). (c) The spin texture $\vec{S}(\boldsymbol{k})$ on the Fermi surface centered at the Y point with hole doping ($E = -0.08$eV). The y and z components ($S_y(\boldsymbol{k})$ and $S_z(\boldsymbol{k})$) are separately plotted. The color represents normalized $S_\mu(\boldsymbol{k})$ ($\mu = y, z$), given as $S_\mu(\boldsymbol{k})/\left(\max_{\boldsymbol{k}} |S_\mu(\boldsymbol{k})|\right)$. $S_\mu(\boldsymbol{k})$ forms an 1D real irrep of mmm.

Under the ambient pressure, $MnGe_3$ has a coplanar triangular antiferromagnetic structure [see Figs. 7 (a) in the main text]. It was found that spin moments acquire an out-of-plane canting angle θ under high pressure, and θ gradually change with the increase of the pressure [3], and the MSG of non-coplanar Mn_3Ge is $C2'/m'$ (No. 12.5.70). Since non-coplanar Structures with different θ ($\theta \neq 0$ or $\pi/2$) share similar symmetries, *i.e.,* are described by the same MSG and SSG, we study the case with $\theta = \pi/4$, without lost of generality. Fig. S.3 (b) shows the energy bands from the first-principle calculation with constrained spin directions. On line A-L ($\boldsymbol{k} = (u, 0, \pi)$), the bands are always two-fold degenerate. However, the little co-group in MSG on that line is m', which only has a 1D coirrep.

The SSG of non-coplanar Mn_3Ge is N194.6.1 $GM5^+$ with the parent space group being $P6_3/mmc$. Its generators are given as $\hat{C}_{6z} = \{e^{i\frac{\pi}{3}\sigma_z}|6^+_{001}|0,0,1/2\}$. $\hat{\mathcal{P}} = \{\sigma_0|\bar{1}|\mathbf{0}\}$, $\hat{M}_x\hat{\mathcal{T}} = \{e^{i\pi\sigma_x}i\sigma_y\mathcal{K}|m_{100}|\mathbf{0}\}$, and pure spatial translation $\{\sigma_0|1|\boldsymbol{a}_i\}$ ($i = 1, 2, 3$). The little co-group of the A-L line is generated by $\hat{M}_y\hat{\mathcal{T}} = (\hat{C}_{6z})^3\hat{M}_x\hat{\mathcal{T}} = \{i\sigma_z\mathcal{K}|m_{210}|0,0,3/2\}$ and $\hat{M}_x\hat{\mathcal{T}}$. We find that $(\hat{M}_y\hat{\mathcal{T}})^2|\psi(u,0,\pi)\rangle = -|\psi(u,0,\pi)\rangle$, leading to the Kramer's degeneracy along line A-L.

$B_{2g} \oplus B_{1u}$ spin texture in $FePO_4$

The compound $FePO_4$ (No. 0.17) crystallizes in a primitive tetragonal lattice and exhibits a coplanar magnetic material described by MSG $P2_12_12_1$ (No. 19.1.119) [4]. The spin moments are confined in x, y plane and are shown in Fig. S.4 (a). The SSG of $FePO_4$ is P62.3.24 $GM3^- \oplus GM4^+$ with the parent space group being $Pnma$. Besides $\mathcal{S}_{Z_2^T}$ [Eq. (5) in the main text] and lattice translations, the SSG is generated by $\mathcal{P} = \{U_{\boldsymbol{y}}(\pi)|\bar{1}|\mathbf{0}\}$, $M_z = \{U_{\boldsymbol{x}}(\pi)|m_{001}|1/2,0,1/2\}$, and $M_y = \{I|m_{010}|0,1/2,0\}$. The unitary lattice translations in this SSG are all accompanied by the identity spin rotation ($T_U = T_M$). Hence, the SSG momentum and crystal momentum are equivalent, and the spin textures in the SBZ and magnetic BZ are the same.

Let us consider the spin texture $\vec{S}(\boldsymbol{k})$ by the method discussed in Sec. III D in the main text. The spin-operation part of the $\mathcal{PT}$ operation is $TU_{\boldsymbol{x}}(\pi)$, which flips the $S_x(\boldsymbol{k})$ and leaves $S_{y,z}(\boldsymbol{k})$ invariant. Consequently, although spin moments are within the x, y plane in real space, the spin texture $\vec{S}(\boldsymbol{k})$'s are confined to the y, z plane in the $\boldsymbol{k}$ space. It is worth noting that this specific $\mathcal{PT}$ operation, which only forbids $S_z(\boldsymbol{k})$ but not the entire $\vec{S}(\boldsymbol{k})$, does not exist in any MSG. Therefore, the confinement of spin moments to two perpendicular planes in real and momentum space is generally impossible with only MSG symmetries. $\vec{S}(\boldsymbol{k})$ respects a point group $\tilde{P} = \{s_g R_g | g \in \mathcal{G}\}$, which is mmm in this case. The SSG requires that under $\mathcal{P}$, $\boldsymbol{S}_y(\boldsymbol{k})$ is odd, $\boldsymbol{S}_z(\boldsymbol{k})$ is even; under M_z (M_y), $\boldsymbol{S}_{y,z}(\boldsymbol{k})$ are both odd (even). Thus, $S_y(\boldsymbol{k})$ ($S_z(\boldsymbol{k})$) forms a real 1D irrep of mmm, refered to as B_{2g} (B_{1u}). The symmetry of $\vec{S}(\boldsymbol{k})$ of this material is also summarized in Sec. G. Then, we compare this analysis with the result of the first-principle calculation.

By the first-principle calculation, $FePO_4$ is identified as a band insulator [Fig. S.4 (b)]. We study the spin texture $\vec{S}(\boldsymbol{k})$ on the Fermi surface ($E = -0.08$eV) with hole doping. The equal-energy surface is centered at Y point ($\boldsymbol{k} = (0, \pi, 0)$) that is mmm-invariant. Although along the path S-Y-Γ [Fig. S.4 (b)], the energy bands are double-degenerate, but this degeneracy does not exist in generic momentum as the square of the $\mathcal{PT}$ symmetry is equal to 1. As a result, two independent hole-type Fermi surfaces exist. The features of $\vec{S}(\boldsymbol{k})$ on two Fermi surfaces are similar, and we show one of them in Fig. S.4 (c). We verify that $S_x(\boldsymbol{k}) \equiv 0$ within the numerical accuracy. The red and blue colors represent the $S_\mu(\boldsymbol{k})$ ($\mu = x, z$) is positive and negative, respectively, which are consistent with the

prediction of SSGs.

Ths spin textures on the remaining Fermi surfaces of example materials

In the main text and supplemental materials above, we showed the spin textures on one of the Fermi surfaces of Mn_3Ge, Mn_3GaN, and $FePO_4$. In the subsection, we present the spin textures on the remaining Fermi surfaces of these materials (see Figs. S.5, S.6, and S.7). One can verify that the symmetries of the spin textures are consistent with the SSG analysis in the main text.

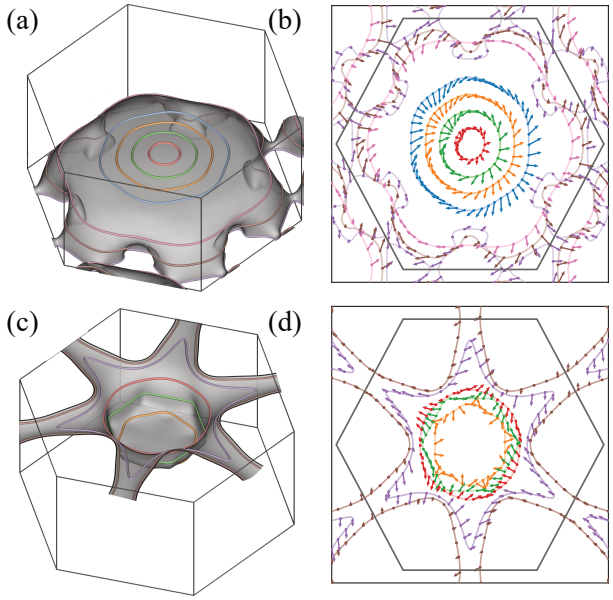

FIG. S.5. (a), (c) The second and third Fermi surfaces of Mn_3Ge. Different colors represent equal-k_z lines. (b), (d) The spin texture $\vec{S}(\boldsymbol{k})$ on equal-k_z lines labeled in the subfigures (a) and (c), respectively. Arrows represent the directions of $\vec{S}(\boldsymbol{k})$.

The spin texture from first-principle calculation with SOC

In the main text, we present the spin texture on the Fermi surface of Mn_3Ge obtained from first-principle calculation without SOC. In the momentum space, the spin texture $\boldsymbol{S}(\boldsymbol{k})$ is coplanar within the x, y plane if the effect of SOC is not included. We find that a tiny $|S_z(\boldsymbol{k})| \approx 1/10|S(\boldsymbol{k})|$ is developed in the first-principle calculation with SOC, because $\mathcal{PT} = \{TU_{\boldsymbol{z}}(\pi)|\bar{1}|0,0,0\}$ is no longer an exact symmetry. However, the spin texture of $(S_x(\boldsymbol{k}), S_y(\boldsymbol{k}))$ shows a similar vortex configuration with charge $S_V = 2$ (Fig. S.8), consistent with the analysis of SSG.

In the supplemental materials above, we study the spin textures of $FePO_4$. The SSG $\mathcal{PT}$ operation $\{TU_{\boldsymbol{x}}(\pi)|\bar{1}|\boldsymbol{0}\}$ require $\boldsymbol{S}(\boldsymbol{k})$ to be confined within y, z planes, as confirmed by the first-principle calculation without SOC. Similarly,

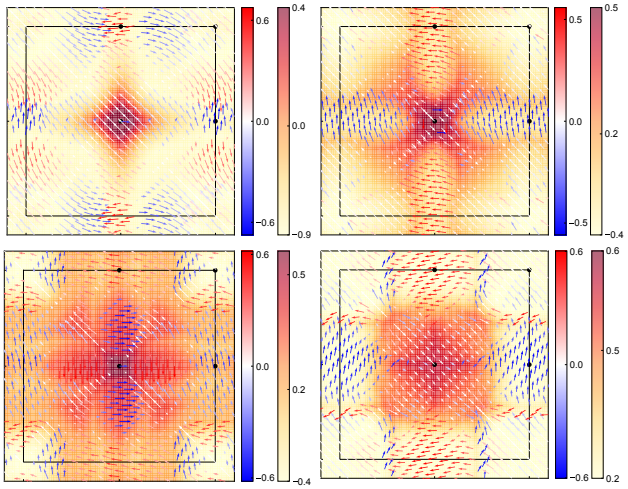

FIG. S.6. The spin texture $\vec{S}(\boldsymbol{k})$ on the $k_z = 0$ (001 plane) in the momentum space of different bands of Mn_3GaN. The background colors denote the values of $E(\boldsymbol{k})$ (see the first color bar on the right). $\vec{S}(\boldsymbol{k})$'s are not confined to the 001 plane, and the red or blue color (the second color bar on the right) represents the value of $S_z(\boldsymbol{k})$.

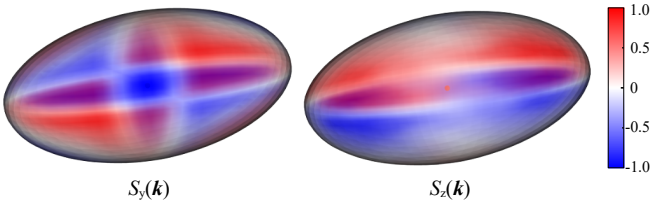

FIG. S.7. The spin texture $\vec{S}(\boldsymbol{k})$ on the second Fermi surface of $FePO_4$. The y and z components ($S_y(\boldsymbol{k})$ and $S_z(\boldsymbol{k})$) are plotted separately. The color represents normalized $S_\mu(\boldsymbol{k})$ ($\mu = y, z$), given as $S_\mu(\boldsymbol{k})/\left(\max_{\boldsymbol{k}} |S_\mu(\boldsymbol{k})|\right)$. $S_\mu(\boldsymbol{k})$ forms an 1D real irrep of mmm.

$|S_x(\boldsymbol{k})| \approx 1/3|S(\boldsymbol{k})|$ is developed in the calculation with SOC, and $(S_y(\boldsymbol{k}), S_z(\boldsymbol{k}))$ shows a similar pattern as the case without SOC. Note that the SOC-induced $|S_x(\boldsymbol{k})|/|S(\boldsymbol{k})|$ here is larger than SOC-induced $|S_z(\boldsymbol{k})|/|S(\boldsymbol{k})|$ observed in Mn_3Ge, which is explained as follows. Despite being in a coplanar magnetic structure, the spin moments of $FePO_4$ predominantly align along the x direction (see Table III). If the y components of magnetic moments were zero, the structure would be collinear anti-ferromagnetic, in which $|\vec{S}(\boldsymbol{k})| \equiv \boldsymbol{0}$. The canting towards the y direction, which induces finite $S_y(\boldsymbol{k})$ and $S_z\boldsymbol{k})$, is a perturbative effect. As a result, $|S_x(\boldsymbol{k})|$ induced by the SOC, which is also a perturbative effect, is not negligible compared to $S_y(\boldsymbol{k})$ and $S_z(\boldsymbol{k})$.

Magnetic moments from first-principle calculations

Table III compares the magnetic structures from DFT calculations to the experimental ones for all the seven materials discussed in this work.

We also perform first-principle calculations with the SOC

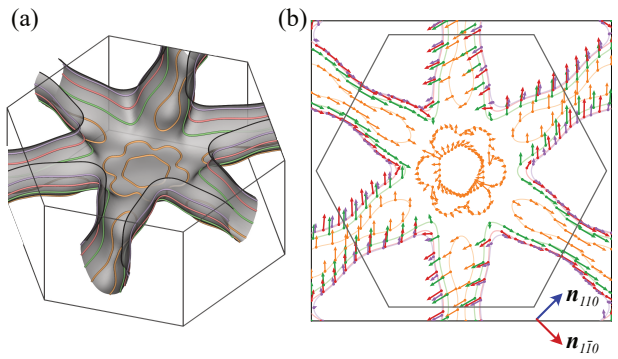

FIG. S.8. (a) The Fermi surface of Mn_3Ge obtained by the first-principle calculation with SOC. Different colors represent equal-k_z lines. (b) The spin texture $\vec{S}(\boldsymbol{k})$ on equal-k_z lines labeled in (a)

TABLE III. The magnetic moments of all the real materials studied in the main text and supplemental materials. The column "DFT" ("Exp") lists the magnetic moments obtained from the first-principle calculation (experimental measurement) with the unit being μ_B. We only list magnetic moments of inequivalent atoms.

E. DIRAC THEORY FOR THE 3D $\mathbb{Z}_2$ TI

In this section, we discuss how the surface Dirac cone of the 3D $\mathbb{Z}_2$ TI emerges by the Dirac theory. Let us consider $y = N_y$ surface of the 3D TI, and its Hamiltonian can be obtained by coupling helical edge modes of the 2D $\mathbb{Z}_2$ TI in different layers:

$$\mathcal{H}_s(k_x, k_z) = \begin{pmatrix} v_F k_x \sigma_z & V_s(k_z) \\ V_s(k_z)^\dagger & -v_F k_x \sigma_z \end{pmatrix}, \tag{S34}$$

where $\pm v_F k_x \sigma_z$ describe the band dispersion of the helical edge states on $z = n$ and $z = n + 1/2$ ($n \in \mathbb{Z}$) planes, and $V_s(k_z)$ describe the hopping between them. This surface and H_s should respect the symmetries $\hat{G}_x = \{I|m_{100}|0, 0, 1/2\}$ and $\hat{M}_z\hat{T} = \{\mathcal{T}|m_{001}|\mathbf{0}\}$. The G_x and M_zT in this basis are given as

$$D_s(G_x) = \begin{pmatrix} 0 & e^{ik_z} \\ 1 & 0 \end{pmatrix} \otimes \sigma_0, \; D_s(M_z\mathcal{T}) = \begin{pmatrix} 1 & 0 \\ 0 & e^{ik_z} \end{pmatrix} \otimes i\sigma_y\mathcal{K}\,. \tag{S35}$$

On the G_x-and-M_zT-invariant line $k_x = 0$, $\mathcal{H}_s(0, k_z)$ satisfies

$$D_s(g)^{-1}\mathcal{H}_s(0, k_z)D_s(g) = \mathcal{H}_s(0, k_z) \quad \text{for } g = G_x, M_z\mathcal{T}\,. \tag{S36}$$

After some algebra, we find that

$$V_s(k_z) = f(k_z)e^{-ik_z/2}\sigma_0\,, \tag{S37}$$

where $f(k_z) \in \mathbb{R}$. The eigenvalues of $\mathcal{H}_s(k_x, k_z)$ are given as

$$E_s(k_x, k_z) = \sqrt{v_F^2 k_x^2 + f(k_z)^2} \tag{S38}$$

As $V_s(0)$ should equal $V(2\pi)$, $f(0) = -f(2\pi)$, which means that a k_0 exists such that $V_s(k_0) = 0$. The Dirac point should be located at $(k_x, k_z) = (0, k_0)$ or (π, k_0).

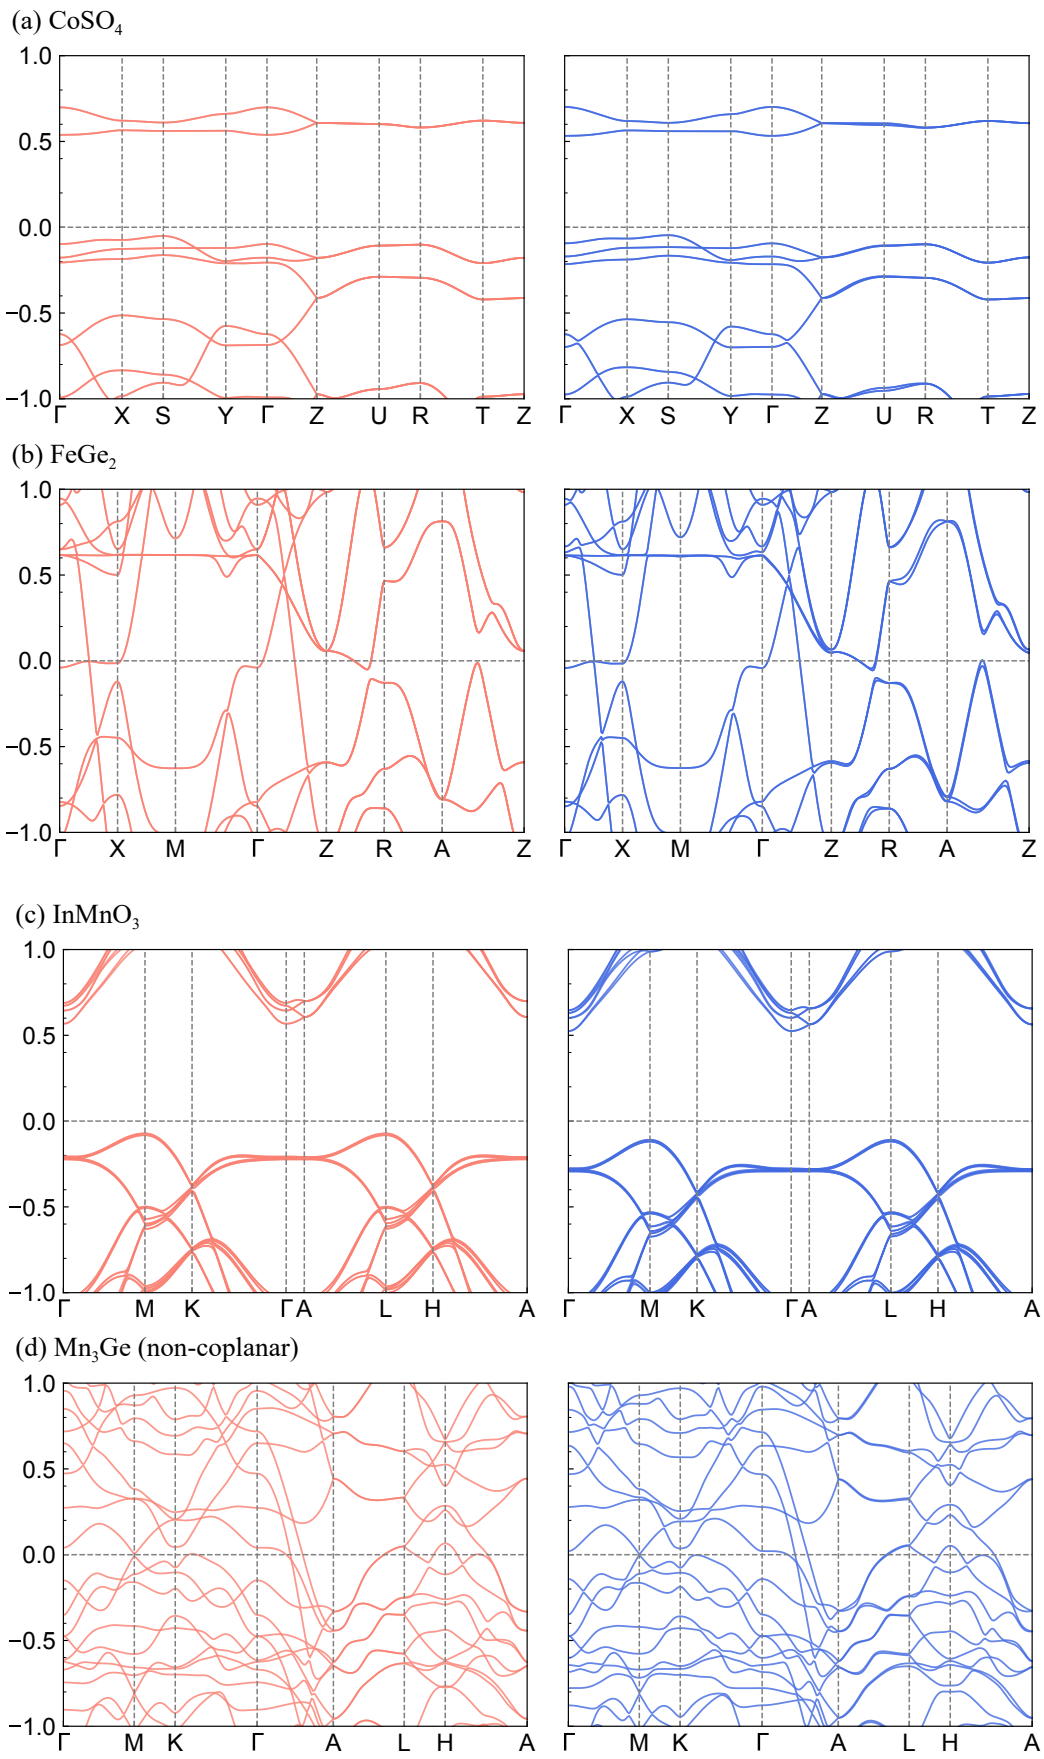

FIG. S.9. Band structures for $CoSO_4$, $FeGe_2$, $InMnO_3$, and Mn_3Ge (non-coplanar). Bands in the left and right columns are obtained without and with SOC, respectively.

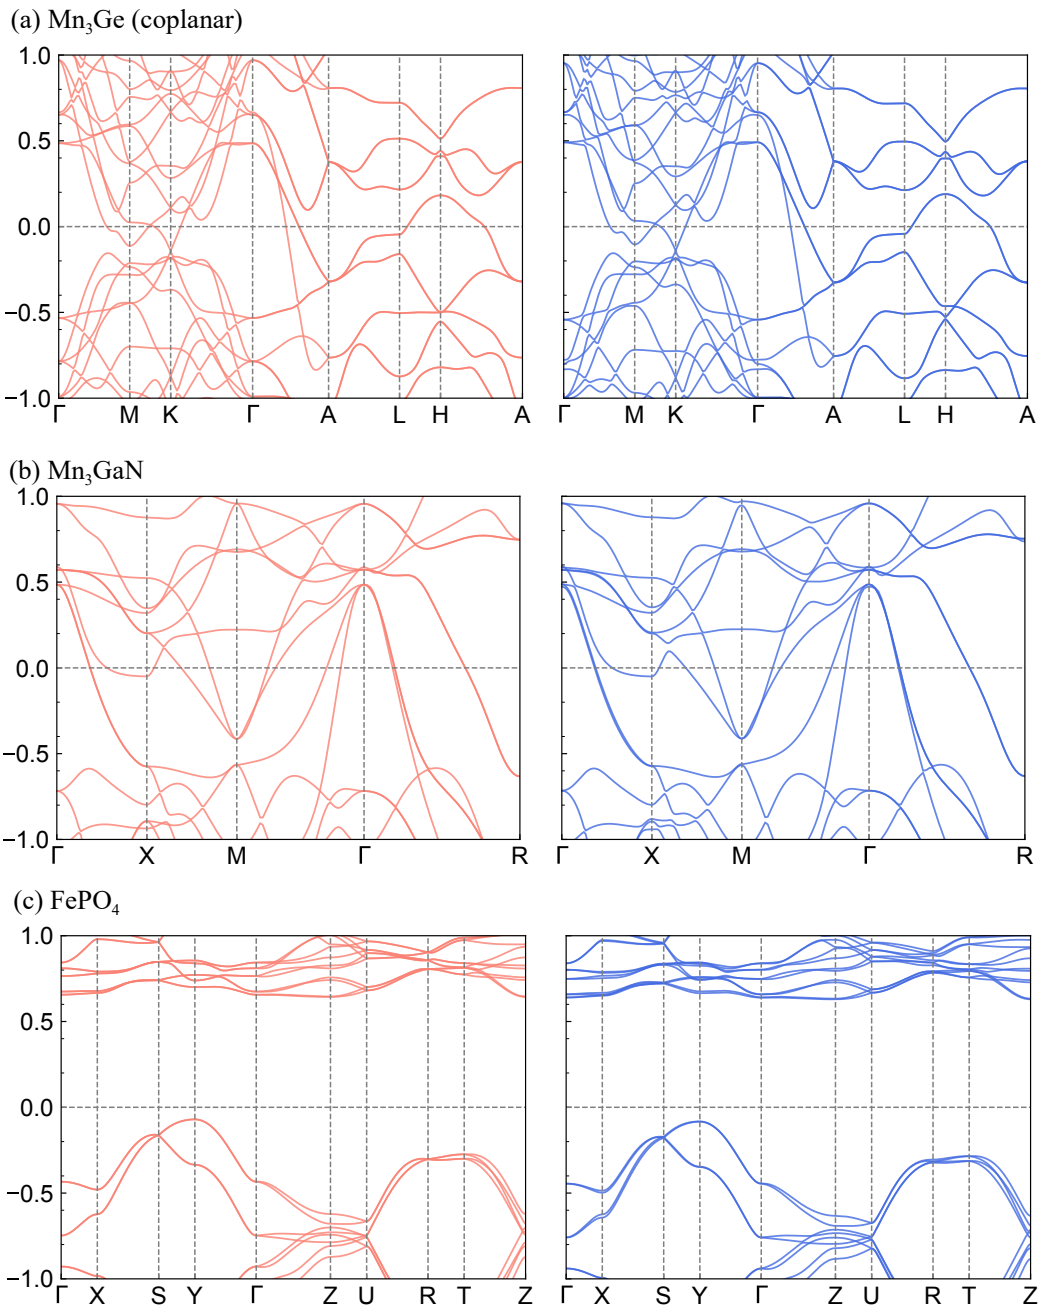

FIG. S.10. Band structures for Mn_3Ge (co-planar), Mn_3GaN, and $FePO_4$. Bands in the left and right columns are obtained without and with SOC, respectively.

F. TABLE OF SSGS

The following tables present all spin space groups (SSGs). The SSGs ($\mathcal{G}$) for collinear, coplanar, and non-coplanar magnetic structures can be represented by O(1), O(2), and O(3) representations of the parent space groups, respectively. For each parent space group, SSGs for the collinear, co-planar, and non-coplanar magnetic structures are listed in the three adjacent tables. The 230×3 tables are arranged in ascending order based on the indices of their parent space groups. Each row in the column "SSG" provides the name of an SSG, in the form $\alpha\mathcal{I}.\mathcal{J}.\mathcal{K}\ \rho$, where α indicates collinear ($\alpha = \mathrm{L}$), coplanar ($\alpha = \mathrm{P}$), or non-coplanar magnetism ($\alpha = \mathrm{N}$), $\mathcal{I} = 1 \cdots 230$ is the index of the parent space group P, $\mathcal{J} = 1 \cdots 16$ is the type of the representation, $\mathcal{K}$ is the additional numbering of the SSG for given $\alpha\mathcal{I}.\mathcal{J}$, and ρ specifies the constituent irreps forming the O(N) representation (see Sec. II E in the main text). The explicit representation matrices of these irreps can be accessed on the Bilbao Crystallographic Server [5]. In cases where several inequivalent O(N) representations correspond to the same SSG, we provide one of them in the table and consistently use the chosen one in the nomenclature. The remaining O(N) representations describing the same SSG can be found in the text files [6].

The additional columns of the tables are the properties of electronic states determined by the SSG and its representation theory. For non-collinear SSGs, if all operations in the unitary translation subgroup T_U commute with each other, the SSG possesses a commuting SSG Brillouin zone (SBZ); it possesses a non-commuting SBZ otherwise. We indicate a commuting SBZ with "$\surd$" and a non-commuting SBZ with "$\times$" in the "Commute" column. In cases of commuting SBZs, the column "d_{SBZ}" ("d_{BZ}") lists the dimension d_{SBZ} (d_{BZ}) of the span of the spin texture $\tilde{\boldsymbol{S}}(\tilde{\boldsymbol{k}})$ ($\vec{S}(\boldsymbol{k})$) in the SBZ (magnetic BZ). Commuting SBZs can be further classified into symmorphic ("$\surd$" in the column "Symmorphic SBZ") and nonsymmorphic ("$\times$") depending on how SSG momentum $\tilde{\boldsymbol{k}}$ is transformed under SSG operations. In a symmorphic SBZ, the momentum transforms normally under the SSG operations, *i.e.,* $\tilde{\boldsymbol{k}} \to \tilde{\boldsymbol{k}}' = s_g R_g \tilde{\boldsymbol{k}}$, with R_g being the point group part of SSG operation g and s_g being 1 (-1) for unitary (anti-unitary) g. The symmetry of the spin texture $\tilde{\boldsymbol{S}}(\tilde{\boldsymbol{k}})$ in the SBZ can be characterized by a d_{SBZ}-dimensional representation $\tilde{\rho}$ of a point group $\tilde{P} = \{s_g R_g | g \in \mathcal{G}\}$. It is also notable that in the cases of symmorphic SBZs, $d_{\mathrm{BZ}} = d_{\mathrm{SBZ}}$, and $\vec{S}(\boldsymbol{k})$ realizes the same representation $\tilde{\rho}$ of $\tilde{P}$ as $\tilde{\boldsymbol{S}}(\boldsymbol{k})$ (see Sec. III D in the main text). The point group $\tilde{P}$ and its representation $\tilde{\rho}$, expressed as a direct sum of the irreps of $\tilde{P}$, are shown in the columns "Sym of $\tilde{\boldsymbol{S}}(\tilde{\boldsymbol{k}})$" and "representations", respectively. We adopted the notations of irreps of crystalline point groups in Ref. [7], where the explicit forms and characters of these irreps can also be accessed. Conversely, in a nonsymmorphic SBZ, $\tilde{\boldsymbol{k}}$ transforms to $s_g\left(R_g\tilde{\boldsymbol{k}} + \tilde{\boldsymbol{q}}_g\right)$, where $\tilde{\boldsymbol{q}}_g$ is not a reciprocal lattice. Characterizing the symmetry of $\tilde{\boldsymbol{S}}(\tilde{\boldsymbol{k}})$ in a nonsymmorphic SBZ is left for future study. For collinear SSGs, electronic Bloch states are effectively described by the linear representations of single-valued grey space groups. It is unnecessary to introduce the concepts of non-commuting or nonsymmorphic SBZ. For collinear SSGs, $d_{\mathrm{BZ}} \leq 1$ because the electronic Hamiltonian can be diagonalized into spin-up and spin-down parts.

G. TABLE OF PUBLISHED MAGNETIC MATERIALS

We identify and show the SSGs of 1595 published experimental magnetic structures in the MAGNDATA database [8, 9] on the Bilbao Crystallographic Server in the following tables. The SSGs of collinear, coplanar, and non-coplanar magnetic structures are displayed in three separate tables. Within each table, the materials are further divided into two groups: light-element materials, where all consistent elements are from the first four periods of the periodic table, and heavy-element materials. The column "BCSID" contains the labels of magnetic structures in the database. The column "MSG" lists the magnetic space group of each magnetic material, using the Opechowski-Guccione notation [10]. "PSG" denotes the parent space group of the SSG. The column "Trans from parent structure" shows the transformation matrix and the origin shift from the paramagnetic structure's cell to the conventional cell of the parent space group. The choice of paramagnetic structures' cells can be found in the magnetic crystallographic information files in the MAGNDATA database. The column "Rep" lists the O(N) ($N = 1, 2, 3$) representation realized by the transformation of the spin moments under operations of the parent space group. The column "SSG" lists the names of the SSGs. Note that inequivalent O(N) representations can describe the same SSGs; hence, the representation in the "Rep" column may differ from the representation in the name of an SSG.

For the convenience of future studies, we prepare additional tables listing all the materials with non-commuting or nonsymmorphic SBZs. We also include tables for materials exhibiting non-zero spin texture $\tilde{\boldsymbol{S}}(\tilde{\boldsymbol{k}})$ ($d_{\mathrm{SBZ}} \neq 0$) with the symmorphic SBZ. The columns "d_{SBZ}", "Sym of $\tilde{\boldsymbol{S}}(\tilde{\boldsymbol{k}})$", and "Representation" denote the same meaning as explained for the tables of SSGs. If the irreps listed in the "representation" column are all trivial irreps, we classify the spin texture as trivial; otherwise, it is classified as non-trivial.

H. NOTATIONS OF SSGS IN THE RELATED WORKS

We note that related works on SSGs were carried out by Chen Fang's [11] group and Qi-Hang Liu's group [12]. In this section, we explain the notations of SSGs they adopted. Their notations of SSGs are related to their classification approach, which is akin to Livtin's (also discussed in Sec. VI in the main text). Litvin's approach involves the introduction of a normal subgroup $P_0 = \{\{R_g|\boldsymbol{v}_g\}|X_gU_g = I, g \in \mathcal{G}\}$ of the parent space group P, consisting of pure spatial operations that leave the magnetic structure unchanged. Additionally, a supergroup $\mathcal{B} = \{X_gU_g|g \in \mathcal{G}\}$ of the pure-spin-operation group $\mathcal{S}$ is introduced, containing the spin operation parts of all SSG operations. P can be decomposed as cosets of P_0

$$P = p_1P_0 + p_2P_0 + \cdots + p_nP_0\ . \tag{S39}$$

Distinct SSGs are defined based on distinct P, P_0 and $\mathcal{B}$, and the isomorphisms between P/P_0 and $\mathcal{B}/\mathcal{S}$, modulo the equivalence induced by coordinate transformation. The group P_0 has a translation subgroup $T_M = \{\{1|\boldsymbol{v}_g\}|X_gU_g = I, R_g = 1, g \in \mathcal{G}\}$ consisting of pure-translation operations, which is also a subgroup of the translation subgroup $T = \{\{1|\boldsymbol{v}_g\}|R_g = 1, g \in \mathcal{G}\}$ of P.

In Ref. [11], the name of an SSG is given by four indices and a letter $N_{\rm SG}.I_k.I_t.N_{\rm rep}.\alpha$. Here $N_{\rm SG}$ is the group index for the parent space group P; $I_k = |T|/|T_M|$, equalling the ratio between the size of the magnetic supercell and the size of the SSG unit cell. The index I_t represents the ratio of distinct point-group operations in P to P_0. The last index $N_{\rm rep}$ specifies the SSGs with the same first three indices, which characterize distinct $\mathcal{B}$'s and distinct isomorphisms between P/P_0 and $\mathcal{B}/\mathcal{S}$. The letter $\alpha = L$ for collinear SSGs, and $\alpha = P$ for coplanar SSGs, while α is omitted for non-coplanar SSGs.

In Ref. [12], the name of an SSG is given by four indices $N_{\rm SG2}.N_{\rm SG}.I_k.m$. Similarly, $N_{\rm SG}$ is the group index for the parent space group, and $I_k = |T|/|T_M|$. The index $N_{\rm SG}$ is the group index of space group P_0 defined before. The last index m specifies the SSGs with the same first three indices. In their nomenclature, they do not specify whether an SSG is for collinear, coplanar, or non-coplanar magnetic structures.

To illustrate the correspondence between their SSG notations and ours, we consider SSG N143.5.1 DT1DU1 (in our notation). As also discussed in Sec. II C in the main text, N143.5.1 DT1DU1 with different momenta $(0, 0, u\pi)$ $[u \in (0, 1)]$ on the line DT1 have different sizes of magnetic supercells, leading to distinct SSGs in their classification. For $\frac{1}{2}u = p/q$ with p, q being coprime integers, the lattice vectors of pure translation group T_0 of this SSG are $\boldsymbol{a}_1, \boldsymbol{a}_2$ and $q\boldsymbol{a}_3$ (see Sec. II C4 in the main text). Thus, the index $I_k = q$. Since the C_{3z} operation in this SSG is accompanied by the identity spin operation, independent of u. The subgroup P_0 is given as $T_0 + T_0C_{3z} + T_0C_{3z}^2$, isomorphic to the space group $P3$ (No. 143). Thus, the index $I_t = 1$, and the group index $N_{\rm SG2} = 143$. Note that the above analysis can only specify the first three indices in their notations, and the fourth index is determined by explicitly considering the spin operations of the generators of the space group. In the case of $u = 2/3$, $I_k = 3$, we find that it corresponds to the SSG 143.3.1.1 in Ref. [11], and corresponds to 143.143.3.1 in Ref. [12]. In the case of $u = 1/2$, $I_k = 4$, it corresponds to the SSG 143.4.1.1 and 143.143.4.1 in these two works, respectively. If $u = 1/6$, $I_k = 12$, it corresponds to the SSG 143.12.1.1 in Ref. [11]. Such an SSG does not exist in Ref. [12] since they only consider the case with $I_k \leq 8$. The SSG N143.5.1 DT1DU1 with $\frac{1}{2}u = 1/p$ and $p > 12$ is only studied in our classification, but not studied in either of their works, because Ref. [11] only consider the case $I_k \leq 12$.

We also map an SSG they study to the notation in our classification (see the related technique in Sec. D). In Ref. [11], the authors study non-coplanar SSG 83.2.4.1 (in their notation) with parent space group $P4/m$ (No. 83). The SSG is generated by

$$\{I|m_{001}|\mathbf{0}\}, \{I|4^+_{001}|\mathbf{0}\}, \{T \cdot U_{\hat{z}}(\pi)|1|001\}, \{I|1|010\}, \text{ and } \{I|1|100\}\ . \tag{S40}$$

Since the corresponding O(3) matrices of translation $\{1|\boldsymbol{a}_i\}$ (i = 1,2,3) are I, I, and $\mathrm{diag}(1, 1, -1)$, respectively. Thus, the momenta of the O(3) representation are $\boldsymbol{k}_1 = \mathbf{0}$ (GM point), $\boldsymbol{k}_2 = \mathbf{0}$ (GM point), and $\boldsymbol{k}_3 = (0, 0, \pi)$ (Z point). Meanwhile, the representation matrices of $\{m_{001}|\mathbf{0}\}$ and $\{4^+_{001}|\mathbf{0}\}$ are both identity matrices. Therefore, this SSG's corresponding O(3) representation is $\mathrm{GM1}^+ \oplus \mathrm{GM1}^+ \oplus \mathrm{Z1}^+$. Since $\mathrm{Z1}^+$ is a 1D real irrep, this SSG belongs to type II and is named N83.2.7 $\mathrm{Z1}^+$. Note that the trivial irrep $\mathrm{GM1}^+$ is omitted in our notation.

In Ref. [12], the authors study SSG 13.54.1.2 (in their notation) with parent space group $Pcca$ (No. 54). The SSG is generated by which is generated by

$$\{U_{\boldsymbol{z}}(\pi)|2_{010}|00\frac{1}{2}\}, \{I|2_{001}|00\frac{1}{2}\}, \{I|\bar{1}|\mathbf{0}\}, \{I|4^+_{001}|\mathbf{0}\}, \{I|1|\boldsymbol{a}_i\}(i = 1, 2, 3)\ . \tag{S41}$$

Since the translations are all accompanied by the identity matrices, the three momenta of the O(3) representations are all $\mathbf{0}$ (GM point). The representation matrices for other operations are diagonal, and hence the O(3) representation is given by the direct sum of three 1D irreps. By studying the explicit forms of spin operations, we find that the O(3) representation is $\mathrm{GM1}^+ \oplus \mathrm{GM2}^+ \oplus \mathrm{GM2}^+$, and the SSG is named N54.3.12 $\mathrm{GM2}^+ \oplus \mathrm{GM2}^+$ in our classification.
